THE RELATIONSHIP BETWEEN DISRUPTIVE BEHAVIOR AND
SOCIO-ECONOMIC STATUS, ETHNICITY, AND SEX OF THE
STUDENT; THE SIZE, LOCATION, AND ETHNICITY OF THE
SCHOOL, IN SELECTED TRI-ETHNIC JUNIOR HIGH SCHOOLS

By

Armando R. Garrido

August, 1978

Chairman: Dr. S. Kern Alexander
Cochairman: Dr. Vynce A. Hines
Major Department: Educational Administration

The purpose of this study was to ascertain whether

there existed significant relationships between disruptive

behavior and the socio-economic status, ethnicity, and

sex of the student; and the location and size of the school.

A secondary purpose was to determine whether there was a

relationship between the ethnicity of the school principal

and the kinds of students who exhibited disruptive behavior.

The sample consisted of 1,080 students drawn from

12 junior high schools in Dade County with a total popula-

tion of 14,281 students. Half of the junior high schools

were located in urban Dade County, a nd the other half were

located in suburban Dade County. Two of the junior high

schools were of small size, 7 were of medium size, and 3

were of large size. Fifty percent (50%) of the principals

were white American, and the other 50% were non-white

American. Ninety students were selected from each school,

comprised of equal number of males and females from each
of the 3 ethnic groups.

During the spring of 1978, questionnaires were used
to obtain measures of socio-economic status, ethnicity, sex,
and disruptive behavior of the students in the sample.
Measures of the schools' characteristics--size, location,
and the ethnic origin of the principal--were also obtained.
Hollingshead's Two Factor Index of Social Position was used
in order to determine the socio-economic status of each
student in the sample. The questionnaires were completed
by the students under the supervision of a guidance coun-
selor. The assistant principal in charge of discipline for
each school reviewed them to ascertain that the information
about the students' school behavior was accurate. Of the
1,080 students selected, 123 were identified as disruptive.

Two statistical techniques were used to analyze the
data in this study. Multiple regression was used in testing
the first hypothesis, and chi square was used in testing
the rest.

Ten conclusions were drawn from the analysis of the
data in this study:

1. The proportion of disruptive lower socio-
economic status students was significantly higher than the
proportions of disruptive middle- and upper-class students.
Furthermore, this variable had the highest relationship
with the incidence of disruptive behavior.

2. The proportion of disruptive male students was significantly higher than the proportion of disruptive female students.

3. The ethnicity of the student was incidental to the incidence of disruptive behavior when socio-economic status was taken into consideration.

4. The proportion of disruptive lower-socio-economic-status male students is significantly higher than the proportions of disruptive middle- and upper-socio-economic-status male students.

5. The proportions of disruptive black American and Hispanic-origin male students are significantly higher than the proportions of disruptive black American and Hispanic-origin female students.

6. The proportion of disruptive lower-socio-economic-status students in schools with white American principals was significantly higher than the proportion of disruptive lower-socio-economic-status students in schools with non-white American principals.

7. The proportion of disruptive black American students in schools with white American principals was significantly higher than the proportion of disruptive black American students in schools with non-white American principals.

8. There was no significant difference in the proportions of disruptive students of different ethnic origins in schools with non-white American principals.

9.   Schools with white American principals identified as disruptive a significantly higher proportion of black American students and a significantly lower proportion of white American students than schools with non-white American principals.

10.   The proportion of disruptive students in the eighth grade was significantly lower than the proportions of disruptive students in the seventh and ninth grade.

CHAPTER I

INTRODUCTION

Disruptive behavior has always been an area of
great concern for educators, not only because society
expects that schools, as one of its institutions, will
play a major role in the socialization process of its
youth, but also because, for the learning process to take
place, it is necessary that the classroom environment be
conducive to education. The educational purposes of the
school are accomplished best in a climate where the duties
and responsibilities of the students and the rules and
regulations of the school are respected.

About a decade ago a major transformation in the
modes of behavior of our youth began to take place, to
the dismay of governmental authorities, parents, and
educators, significantly increasing the generation gap.
The emphasis on guaranteeing the constitutional rights
of students and minorities, the drastic changes brought
about by recent Supreme Court decisions upon the procedures
for controlling students' behavior, the Viet Nam War and
the anti-war demonstrations, the assassination of poli-
tical and civic leaders of the sixties, violence on
television, the increase in the divorce rate and in the

1

number of homes where both parents work, and the rapid evolution of our youth culture have all been factors which have produced a shattering impact upon student behavior.   In fact, although disruptive behavior is not new to American schools, it has become more frequent and has involved a greater number of students.

In Florida, the problem of disruptive behavior in the schools has affected every school district and has resulted in fiscal and human capital losses to the state.   Because of this, in 1973, The Governor's Task Force on Disruptive Youth was created to conduct studies throughout the state.

During the junior high grades, students experience a drastic change in the rate of physical growth and for them reaching puberty has great physiological and psychological implications.   This period of time in a student's life is considered the most difficult one in all grades, K through 12 inclusive.   Because of these changes,it is in the junior high school where students manifest the most behavioral problems.

Many hypotheses have been formulated on the subject of disruptive youth in schools.   Several of them shall be examined in an attempt to arrive at some qualified, enlightened answers.   Hopefully, if factors that cause disruptive behavior can be identified, then measures may be taken to prevent its occurrence.   It is

usually easier and preferable to take preventive measures
to solve a conflict of this nature than it is to try to
arrest the problem once it has erupted openly. Disruptive
behavior not only interrupts the learning process within
the classroom, but in the more serious cases may result
in the forceful removal of the student from the classroom.
It follows that his removal from the academic environment
necessarily has deleterious effects upon his learning
process. The more times the suspension occurs, the less
probable that the student eventually will catch up with
his/her school work. Expulsion is a more serious matter
because it denies the youth the opportunity of rehabilita-
tion, at least within his/her own environment.

Nature of the Study

This study was an associational study of various
student characteristics, some junior high school char-
acteristics, and student suspensions during the first
eight months of the 1977-78 school year. Twelve of the
forty-six junior high schools in Dade County participated
in the study. Each of the schools had a representative
population of white Americans, black Americans, and
Hispanic origin students. Three variables of the students--
ethnicity, socio-economic status, and sex, together with
three variables of the school--size, location, and ethnicity
of the principal, were analyzed with the frequency of student

suspensions and statisfically tested. Hollingshead's
Two Factor Index of Social Position was used to
determine the socio-economic status of the students.

Statement of the Problem

The primary purpose of this study was to
attempt to ascertain whether socio-economic status,
ethnicity, and sex of the student, and the location
and size of the school can be predictors of disruptive
behavior in tri-ethnic junior high schools, of white
American, black American, and Hispanic-origin
students.

A secondary purpose was to discover whether
there is a relationship between the ethnicity of the
school principal and the kinds of students who exhibit
disruptive behavior. More specifically, this research
sought answers to the following questions:

1. What is the difference in the number of
disruptive students of lower, middle, and high socio-
economic positions in junior high schools?

2. What is the difference in the number of
disruptive students of white American, black American,
and Hispanic-origin students in junior high schools?

3. Is there any difference in the incidence
of disruptive behavior between male and female students
in junior high schools?

4. Is there a difference in the number of disruptive students in urban and suburban junior high schools?

5. Is there any difference in the incidence of disruptive behavior in small, medium, and large size junior high schools?

6. Does the ethnic origin of the school principal have any effect upon the kind of students who exhibit disruptive behavior in junior high schools?

Limitations of the Study

Three limitations were recognized in this study:

1. The results of this study have validity only concerning disruptive behavior in tri-ethnic junior high schools in Dade County, Florida.

2. The information contained in the questionnaires was accepted as accurate.

3. No consideration has been given to whether teacher effectiveness is related to disruptive acts occurring in the classroom.

Definition of Terms

A disruptive student was operationally defined as any junior high school student who is removed from

the school environment for behavior reasons during the first eight months of the 1977-78 school year.

A junior high school student was operationally defined as any student in the seventh, eighth, or ninth grades of a junior high school.

A Hispanic-origin student was operationally defined as any student born in a Hispanic country or of Hispanic descent.

An urban junior high school was operationally defined as any junior high school in Dade County within a six-mile radius from downtown Miami.

A small size junior high school was operationally defined as one with a school population of less than 1000 students.

A medium size junior high school was operationally defined as one with a school population of between 1000 and 1499 students.

A large size junior high school was operationally defined as one with a school population of 1500 or more students.

Sampling

A stratified random sample of equal numbers of male and female students from each ethnic group (white American, black American, and Hispanic-origin) was drawn from a computer printout by ethnic origin of the

student population of each of the twelve junior high schools selected. The sample of each of the twelve junior high schools selected in this study contained:

     15 male white American students

     15 female white American students

     15 male black American students

     15 female black American students

     15 male Hispanic-origin students

     15 female Hispanic-origin students

Data Collection

A questionnaire was used to gather the data needed for this study (see Appendix). It had the student's name at the top. This questionnaire indicated that the student's name should be detached from the form before it was returned, because of a requirement of the Dade County Schools Research Committee designed to maintain the privacy rights of the students involved in studies. The questionnaire provided the following information.

1. grade

2. sex

3. ethnicity

4. occupation of the student's father

5. occupation of the student's mother

6. level of schooling completed by the student's father.

7. level of schooling completed by the student's mother

8. whether the student had been suspended

9. ethnicity of the school principal

10. name of the school.

Significance

In the ninth annual Gallup Poll of the public's attitude toward the public schools, discipline (disruptive behavior) was singled out as the major problem confronting the public schools of the nation.

This study increased the existing body of knowledge about the relationship of socio-economic status, ethnicity, and sex of students, the ethnicity of the principal, the size and location of the junior high school, and disruptive student behavior. There had been some research done on disruptive behavior previously, but little or none had been done in a tri-ethnic setting. The findings of this study have practical significance for educators who practice their profession in urban and suburban, multi-ethnic settings and in particular for those educators working in Dade County, Florida. The results of this study will be made available for sharing with any and all interested educators.

Organization of the Study

This introductory chapter has included the state-
ment of the problem, the nature, limitations, and signifi-
cance of the study, as well as the method of sampling and
data collection. Chapter II will include the review of
the literature. The design of the study will be discussed
in Chapter III. Chapter IV will present the results of the
study, and the summary, discussion, and conclusions will
be presented in Chapter V.

CHAPTER II

REVIEW OF THE LITERATURE

The major concern of this study is the relationship
between disruptive behavior and socio-economic status,
ethnicity, and sex of the students; and the location,
size, and ethnicity of the principal of the school.

A review of the literature found no study in-
corporating these variables, but it yielded many studies
about disruptive behavior some of which incorporate one
or more of the variables.

The literature on disruptive behavior has been
varied. Studies have been conducted in such areas as pre-
vention and identification (Gloeckler et al., 1968; Mussman,
1968; Hegstrom and Hugh, 1969; Nelson, 1971), behavior
modification techniques (Edwards 1968; Casstevens, 1969;
Wodarski, 1970; Burrows, 1971; Starky, 1973), perceptions
(Mendell, 1968; Driscoll, 1970), activism (Erickson et al.,
1965; Trump and Hunt, 1969), school discipline (Kounin,
1970), mental retardation (Szurek and Berlin, 1968),
social class (Warner, 1949; Hollingshead, 1949; Davis,
1953; Conant, 1961), ethnicity and ethnic composition
(Blake, 1960; Smith, 1962; Gurin, 1966; West, 1966), emo-
tional disorders (Hewett et al., 1967; Braun and Lasher,

1970), juvenile delinquency (Block and Flynn, 1956;
Reckless and Dinitz, 1972), delinquency and self-concept
(Balester, 1956; Atchinson, 1958; Scarpitti, Murray,
Dinitz, and Reckless, 1960; Lively, Dinitz, and Reckless,
1962; Lefeber, 1965; Fitts and Hamner, 1969), and
autistic children (Bosch, 1970).

Literature on Disruption

The Ninth Annual Gallup Poll of the Public's
Attitudes Toward the Public Schools (1977) reported
the highest percentage yet recorded of parents of public
school students citing discipline as the number one
problem in the schools, with integration/segregation/
busing being in second place, and lack of proper financial
support in third.

A study of the experience of teachers with dis-
ruptive behavior in the Dade Public Schools (1976) reported
that the junior high school teachers spend a considerably
greater proportion of their time in dealing with disruptive
behavior than elementary and senior high school teachers,
with 12.2 percent being struck by students, 39.6 percent
being threatened by a student with physical harm, and
72.7 percent having their instructional process completely
disrupted.

Duke (1978) reported that administrators of
urban and non-urban high schools in California and New York

identified truancy, skipping, and lateness to class as the three most pressing discipline problems. He also indicated that most administrators found themselves not enforcing school rules consistently.

In contrast, King-Stoops and Meir (1978) listed fighting, lack of respect for selves, other students, and teachers, and destruction of school materials and profanity among the 10 more important discipline problems identified by teachers.

Student teachers, in a study conducted by Driscoll (1970) identified failure to follow directions, making noise in the halls, whispering, talking in class, and chewing gum among the most frequent types of disruptive behavior. Being under the influence of narcotics, stealing, starting fires, and bomb threats were identified among the most serious offenses.

In a study on early identification of children who are likely to display poor social adjustment, low academic achievement, and/or delinquency, Feldhusen (1971) found that classroom behavior traits, arithmetic achievement, child's parents' marital relationship, and maternal discipline were predictors of late social adjustment. Teacher ratings of social adjustment, I.Q., sex, parents' educational level, and classroom behavior were found to be predictors of academic achievement.

The purpose of a study conducted by Feldhusen, Benning, and Thurston (1964) was to link elements of students' backgrounds with school misbehavior. After analyzing the home environment of students who exhibited disruptive behavior in the classroom, some psycho-social correlates of misbehavior were found:

1. The discipline of the father was either too lax or too strict, and the supervision of the mother was inadequate.

2. The parents were indifferent or hostile toward the student, and the family lacked unity.

3. The parents were not close and found it difficult to discuss the child's problems.

4. The parents disapproved of many things in their child and were not happy with the community where they lived.

5. Both parents believed they could not influence the development of their child and resorted to angry corporal punishment when disciplining their child.

6. The parents' leisure time activities did not help the social development of the child; as a result of this attitude they thought that other children were bad influences upon their child.

In a more recent study, they also discovered that boys prone to delinquency achieved less in mathematics than the non-delinquency-prone boys, and the former were ranked much lower in their graduating class than their counterparts.

Kaga (1972) pointed out that twelve-year-olds are presented by Western society with local phenomena surrounding school, drugs, sexuality, authority, and family, each of which generates uncertainty that the child must resolve. Contemporary fifteen-year-olds are waging a war against feelings of isolation and are rendered anti-social as a paradoxical reaction to these feelings. Racial strife, density of population, and even more important, lack of values and central ideology, continue to loom as potential catastrophies in the future and, of course, often result in disruptive behavior.

S. R. St. J. Neill (1976) used etiological methods previously applied mainly to young children (Blurton-Jones, 1972) with pre-adolescent boys in a playground situation. These methods were well suited to the playground situation because of the ease of observation without disturbance and because of the range of behavior shown and its dominance in such a situation over verbal communication. The older boys presented a greater incidence of violent behavior and fighting, suggesting that age may be a possible variable in the prediction of disruptive patterns of behavior.

Miller (1974) reported that the average juvenile delinquent has an I.Q. of 95 and is two to four years below his potential by the time he has been in the public schools for seven years.

Twelve principals from a midwest city system met briefly with a number of professors and administrators from the College of Education of the Ohio State University, as reported by Cunningham (1969). The Dean of the College of Education, in an objective report of his experience as an inner city junior high school principal, observed the phenomenon of the principal in relationship to disruptive behavior in the school. There had been a faculty walk-out previously due to school conditions. The students were mostly black. Absenteeism prevailed. About one-fifth of the entire student body was absent every day. The only time students showed up was at lunch time in many cases. Lunch was partly federally funded. Students came into the school building in spite of guards, had their lunch, and went out into the street again. Absenteeism among the school's eighty-five teachers was quite prevalent also. Fights broke out quite frequently. One teacher had been shot ten days before the author arrived on the scene. He had been held up on the street, adjacent to the school, and shot with a pellet gun.

Duke (1976) examined the issue of who misbehaves in the article by that title. In considering a wide range of variables, it was found that students were apt to show evidence of dirsuptive behavior if they had instances of failure in elementary school. He also

stated that there is a positive indication that
disruptive behavior and intelligence are inversely
related, i.e., the more intelligence, the less the
likelihood of showing disruptive behavior and vice
versa. The final words of the article point out the
need for further research to wit: research concerning
itself with "real world" types of investigation rather
than more esoteric "unreal" types of research. The
author also points to the fact that researchers should
not be banned from the schools only because of the
sensitive nature of the schools's discipline.

Redl (1975) was saddened at the fact that
disruptive behavior results in suspension and
expulsion which, in turn, create hostility and result
in more disruptive behavior. Only when a child and
his environment are so badly matched that continuation
would present the possibility of life-long scars should
the child be removed from his learning environment.

Henning (1949) distributed questionnaires to
twenty-five high school principals and asked them about
the extent and seriousness of student misconduct. It
is significant to note that twenty-eight years ago the
most serious offenses were considered to be lying, petty
theivery, and getting together in halls and lavatories.
These examples of misconduct seem hardly worthy of
mention in today's more violent school environment.

We can contrast the above with the findings of
Cutts and Moseley (1957) who cited the most common
instances of misbehavior as the following: talking,
physical attack, unexcused absences, throwing things,
and physical activity. They also listed items as
diverse as chewing gum and immorality as examples of
disruptive behavior.

Studying the different perceptions of disruptive
behavior among secondary school teachers, counselors, and
deans, Mendell (1968) found that deans chose more severe
punishments for disruptive students than did secondary
school teachers and counselors. The older the teacher
the more severe disciplinary measures recommended. Male
educators chose greater penalties than female educators.
He also pointed out that educators chose more severe punish-
ment for male students than for female students.

The National Institute of Education (1977)
conducted a study to determine the frequency and serious-
ness of crime in elementary and secondary schools in
the United States.

The study was divided into three phases. In
Phase I more than 4,000 school principals were asked to
report, through a mail survey, the incidence of illegal
or disruptive activities in their schools. The parti-
cipating schools were chosen at random.

In Phase II, field representatives conducted on-site surveys of a representative sample of 642 junior and senior high schools. Principals, teachers, and students were surveyed. They also reported information about themselves, their schools, and their communities.

In Phase III, a more intensive study of ten schools was conducted. These ten schools had been identified as having a history of crime and violence but had shown a dramatic improvement in a short time.

Some of the most important findings of the study were, in summary, the following:

1. In school, risk of violence to teenagers is greater than elsewhere.

2. The larger the community, the greater the proportion of schools having a serious problem.

3. Higher levels of school crime are reported in secondary schools than those in elementary schools.

4. The proportion of teachers attacked is smaller in rural areas and in senior high schools than in large cities and in junior high schools.

5. In secondary schools, personal violence and vandalism are much more prevalent than in elementary schools; on the other hand, in senior highs and junior highs the incidence of property offenses is about the same, although personal violence is most pronounced in junior highs.

6. The classrooms are the safest places for students in school with high risks during the between-class rushes in hallways and on stairs.

7. Taking all factors into consideration, there is no apparent relationship between a school's racial/ethnic composition and the risk of violence there.

8. More violence and vandalism are experienced in larger schools and schools with larger classes.

9. Students' feelings of frustration can erupt in violence if students do not feel that their courses are relevant and that they have some control over school events.

10. The most likely violent students are those who give up on school.

11. A key factor in reducing violence seems to be a consistent system for running a school were known rules are firmly and fairly enforced.

12. A central conclusion is that the principal's role appears to be a critical factor in that the principal's leadership and initiation of a structure of order seem to differentiate safe schools from unsafe ones.

13. As found, the principal's ability to initiate a structure of order in the school is equally important to his/her personal style of leadership, especially with fair, firm, and most of all, consistent action on his/her part.

A perusal of Dissertation Abstracts yielded some studies on disruptive behavior. Burrows (1971) investigated the effects of systematic changes in the levels of teacher approval on students' disruptive behavior and self-concepts. In one classroom the teacher eliminated approval for three weeks. In another classroom the teacher increased the approval level for six weeks. In classroom No. 1 a functional relationship between levels of teacher approval and student disruptive behavior was demonstrated. In classroom No. 2 a decrease in teacher approval resulted in no significant changes in disruptive behavior nor self-concept. No associations were found between self-concept changes and achievement, intelligence, socio-economic status, or sex.

Hendrix (1970) stressed the need for able and dedicated teachers who know the ghetto and its problems and understand the psychological and social deficits of these students. Studying the causes of why inner city children do not achieve as well as others, he found, "Discrimination and racism, family disorganization, poor self-image, white colonial middle-class schools in Black ghettos, and inadequate teachers are documented as some of the most significant causes of this failure" (p. 283).

According to his findings, some of the most important needs of inner city students are: "(a) positive self-image, (b) expanded aspirational level, (c) success

experiences, (d) peer group encouragement of academic success, (e) exposure to black culture, and (f) an understanding of the general culture" (p. 283).

In a study of how students' misbehavior was perceived by teachers in the Michigan Public Schools, Teitelbaum (1970) found that the teachers perceived the most serious and most frequent disruptive behavior involved students' relationships to other students, followed by violations of school authority.

In a study designed to clarify the conditions that determine teachers' behavior in their reaction to child misbehavior, Victor (1970) reported that while his study yielded no statistically significant findings, there were a number of significant trends. Individuals who scored higher in teacher direct attitudes participated more in misbehavior. Furthermore, this difference was the result of non-verbal behavior. The high conceptual level teacher direct group gave more positive sanctions than any other group and no differences were found between personality and attitude, and the adaptability index.

Wodarski (1970), in a study to determine to what extent behavior modification techniques, based on Skinner's operant theory, were successful in helping to improve non-studying and disruptive behaviors in ghetto schools, found that the introduction of behavior modification

techniques resulted in high rates of studying behavior and low rates of non-studying and disruptive behaviors.

The purpose of a study by Niewiadomski (1971) was to determine student perceptions of school discipline practices, the seriousness of the information, and the fairness and the effectiveness of disciplinary actions. He reported that disciplinary practices in the school studied were found to be moderate, with the use of drugs, destruction of school property, and stealing the most serious discipline problems. Disciplinary actions were found to be fair except in cases of disrespect to teachers, forging passes, and stealing. The disciplinary actions were found to be effective except in cases of gambling, lying, and stealing.

Morgan (1955) compared social background of parents with their attitudes on matters of high school discipline, punishment methods, and positive concepts of discipline. He indicated that there seems to be little difference in attitudes by social background factors except in the categories of occupation, family income, and education.

> The greatest number of differences occur in the application of methods of punishment to specific offenses. The least number of differences occur in connection with the positive concepts of discipline. The variety of punishments endorsed seemed to increase directly with the amount of education and the amount of family income. Among the occupational groups, the business and professional parents are most tolerant toward today's youth and least inclined toward severe measures. (p. 756)

In "An Analysis of Personality and Demographic Factors Concerning Students Involved in Disciplinary Problems," Bealer (1967) found that the variables of more significance to discrimination were personal education aspiration, peer parental relationships, rank in class, and impulse expression for males, and involvement in extracurricular activities, rank in class, and religious attendance for females. If individuals' scores were low, it was quite likely that they would be involved in disruptive behavior. The opposite resulted for individuals with high scores.

Bloom (1964), studying the attitudes of mentally retarded students, concluded that there were significant differences in responsibility, emotional stability, self-regard, and attitudes toward work that were attributable to education alone. Life style was a significant predictor of attitudes towards frustration tolerance, schools, and teachers. There were no significant differences among ethnic groups.

Cummins (1964) investigated the effective and cognitive characteristics of disruptive students. He reported no difference in the cognitive characteristics of disruptive and non-disruptive students. It was also found that affective characteristics did not differ in disciplinary and non-disciplinary students. He concluded that disciplinary and non-disciplinary students are

essentially similar in their affective and cognitive characteristics.

Scurry (1976), studying the relationship among black senior high school students and their perceptions of alienation and internal and external control, indicated:

1. Disruptive high school students perceived themselves as more alienated than the non-disruptive high-school students.
2. Disruptive high school students did not perceive themselves anymore internal-external than the non-disruptive high school students. (p. 3541)

Wilde (1976) sought to determine the efficacy of punishing videotaped models as a tool to diminish the incidence of disruptive behavior in two junior high school classes. He concluded that modeled punishment had no effect on the incidence of disruptive behavior upon the experiment's subjects.

Literature on Socio-economic Status

Coleman (1966) found in his famous study, that all schools are very similar in the way they affect achievement when the socio-economic background of the students is taken into consideration. He also observed that socio-economic factors have great importance in predicting academic achievement. Furthermore, he reported that the family economic level has the highest relation to achievement for all minority groups.

Minority students also are more affected by the quality
of the school they attend:

> The average white student's achievement seems
> to be less affected by the strength or weakness
> of his school's facilities, curriculums, and teachers
> than is the average minority pupil's. To put it
> another way, the achievement of minority pupils
> depends more on the schools they attend than does
> the achievement of majority pupils. (p. 22)

Hollingshead (1949) noted that the higher rate
of failure among lower class students is the combined
result of the values of the lower class students and the
bias of the teachers who are more inclined to extend
extra help to middle and upper class students.

Hindelang (1971) considered age and sex as
variables in studying the versatility of delinquent
behavior, i.e., whether children engaging in delin-
quent behavior tend to perform a wide variety of acts
or whether they confine themselves to a very narrow range
of acts. He found that females tend to engage in a wider
variety of delinquent acts than males and that males tend
to engage with greater frequency than females in street-
gang-related delinquencies. His study was supportive
of the belief that socio-economics may play a part in
disruptive behavior, because street gangs tend to exist
in lower socio-economic neighborhoods.

Reissman (1953) addressed the problem of the
relationship between aspiration and socio-economic

status. A person's peer group has an effect on the interchange between social situations and aspiration levels.

McPartland and McDill (1975) of the Center for Social Organization of Schools, Johns Hopkins University, pointed out that "a student's success and status in school have a unique relationship with the probability of serious offenses, over and above what is accounted for by family background and academic ability" (p. 10).

An article by Lufler (1978), reporting the results of a two-year study conducted by the Center for Public Representation in Madison, Wisconsin, pointed out that teachers felt "discipline problems are an extension of out-of-school problems" (p. 424). The study also found that most of the disruptive students came from single-parent homes, from low socio-economic status homes and/or from families that move frequently. Data analysis revealed that disruptive students tended to receive lower grades and were less involved in school activities.

Brookover et al. (1967) concluded that the influence of self-concept on achievement was possibly greater than that of mental ability. In previous

studies (1964 and 1965), he and others had found that a student's overall ability self-concept is related to his achievement in school. Cook (1970) found that black, low socio-economic, disadvantaged students had significantly lower self-concepts than those of their white counterparts. Branch (1974) discovered that disruptive students in middle schools had lower self-concepts than those of non-disruptive students in the same school environment.

Jencks (1972) pointed out that there are many who believe that the school cannot improve the achievement of the disadvantaged students, that academic performance is predetermined by the socio-economic status of a student's parents.

In the study "Toward Equal Educational Opportunity" (1972), conducted by the United States Senate Select Committee on Equal Educational Opportunity, it was observed that advantaged children and children from deprived homes begin their education at different starting lines:

> A child's socioeconomic status, his parents' educational level and occupational status, the extent to which he and his family are the victims of racial discrimination and all the other elements of his home environment determine in large measure his performance in school and his success or failure in life. (p. 5)

An article by Pearl (1965) observed that:

> . . . There appears to be a general consensus that low income youth, when contrasted with

> more affluent counterparts, are characterized
> by the following: a poorer self-image, a greater
> sense of powerlessness, a more fatalistic
> attitude toward life, a lack of future orien-
> tation, and a greater potential for impulsive
> "acting out." (p. 89)

This statement is highly significant since it singles
out a variable, low income, as the most important factor
in developing the attitudes most often associated with
disruptive youth.

There is no doubt that all the variables are
somewhat interrelated. The question becomes how to
rank them in order of their importance as predictors of
disruptive behavior.

According to Sexton (1961) the failure rate
among elementary school children whose families earned
$3,000 or less per year was six times greater than
the failure rate among those families earning $9,000
per year. This disproportion in the figures cannot be
attributed adequately to mere chance. Some of the
students falling in the lowest income-level families
had children manifesting serious behavior problems--
failing in elementary school studies and engaging in
disruptive behavior--while no problem children were
found among the families within the highest income
bracket.

An article by Miller (1958) about the etiology
of delinquency suggested that adolescent members of

street corner groups in lower class communities,
commit delinquent acts in an attempt to adhere to the
forms of behavior and to the standards of value of
their community. The article further concluded that
"many lower class individuals feel that their lives
are subject to a set of forces over which they have
relatively little control" (p. 11) and therefore when
they are faced with alternatives of accomplishing similar
objectives, the non-law-abiding avenue offers greater
and faster return for a smaller investment of their
energy.

Schonfeld (1968) contended "socio-economic
affluence has been found to play an important prepara-
tory and determining role in how youth copes with his
adolescent crisis" (p. 492). Does this mean that
high income youths are definitely better adjusted than
their lower income counterparts? Not necessarily;
it means only that several factors come into play when
there is definite family affluence, which the low
income youth does not have. He added that these
factors include the extent to which each youth derives
consequences from unsocial or anti-social behavior,
i.e. in the case of a high-income family adolescent,
his likelihood of escaping repercussions from such

acts, since the family usually has the means to retain,
and does indeed retain, skilled lawyers, or possibly pay
damages, causing charges to be dropped through techni-
calities, is a possibility not available to lower-
income-family adolescents. On the other hand, the
lower-income-family youth almost inevitably has to
shoulder the responsibility for his actions.

Erickson (1973) considered the importance of
socio-economic status in his carefully worded article,
"Group Violations, Socioeconomic Status, and Official
Delinquency." The author makes a point of emphasizing
that almost all delinquent acts are those (1) stem-
ming from lower class children, (2) are a group
event predominantly. The first part of this hypoth-
esis exactly agrees with this researcher's view-
point. The article outlined the study conducted to
prove the validity of his hypothesis. Violations of
the law by lower class boys are more frequent than
violations by higher and middle class boys. This seems
to be a pattern that carries over into the adult world.

There is also evidence that lower socio-economic
children tend to accrue more arrests and convictions
than their higher socio-economic-status counterparts.
Erickson supported this tenet by actually quoting a
figure of 11% greater proportional share of arrests

for all offenses for low socio-economic-status children as
compared with 9% less than their proportional share for
middle-class-status children. Higher class children
unaccountably accounted for a slightly lower than their
proportional share of arrests (less than 2%).

Literature on Ethnicity

The Governor's Task Force on Disruptive Youth
(1973) studied the demographic aspects of disruptive
youth in order to be able to determine the significance
of demographic variables in relationship to disruptive
youth in the schools of the State of Florida. Academic
variables, race, and socio-economic variables were
grouped together as the most prevalent factors. The
study suggested that:

> . . . if a pupil was male, black, had a low sixth
> grade test score, a low grade point average, a low
> verbal aptitude score and had not been referred
> for psychological services, he was more likely to
> become a disruptive student and be either expelled
> or suspended from school. (p. 9)

Zirkel and Gable (1977) conducted a study to
examine the test-retest reliability and construct
validity of selected types of self-concept measures.
These were non-verbal, verbal, and pictorial scores and
observer ratings for black, Puerto Rican, and white
adolescents. Results of these measures showed black

students received a greater number of poor ratings and
evidenced poorer self-concepts.

Walberg et al. (1974) reported that while blacks
rated higher in offenses such as driving without a license,
skipping school, and beating up and threatening others,
the incidences of the offenses did not show significant
differences between blacks and whites. He also observed
that there is ethnic bias in the recording and disposition
of juvenile cases.

Higgins (1974) proposed that one focus of pre-
and in-service training should be the development of more
precise objectives for the work of desegregation. In
view of all the desegregation-generated hostility caused
by placing poor black students in middle-to-high class
neighborhood schools, the value of busing seems to be
offset by the increase in disruptive behavior.

Studying group disorders in the public schools,
Ritterband and Silberstein (1973) found that the
presence of black teachers slightly inhibited the occur-
rences of non-political disorders. They also observed
that:

> Equally plausible is the notion that
> disorder occurs when inexperienced teachers
> (who tend to teach the non-white pupils) cannot
> capture their pupils' interest and/or cannot
> control them. . . . however, no matter what
> the school characteristic, whether size
> (presumably implying bureaucratization and
> impersonality) [or other factor]. (p. 466)

Williams and Gold (1972) found that "white girls are no more or less frequently or seriously delinquent than black girls; and white boys, no more or less frequently delinquent than black boys" (p. 215). They further pointed out that whether a policeman chooses to ignore or not to ignore delinquent behavior may be contingent on such factors as the juvenile's sex, race, and social status. The same factors affect the citizen making the complaint.

White (1968) examined the situation in which urban high school students were observed on the basis of many variables, including (1) father's race; (2) mother's race; (3) father's and mother's occupational prestige; (4) father's and mother's education; (5) grade in school; (6) grade point average, (7) sex. The findings about race evidenced that black students were more alienated than white youths; black females evidenced more alienation than males.

<u>Literature on Sex</u>

Touliatos and Lindholm (1976) reported that being a female student in regular classes was a predictor of good behavior, being a male student from a high-social-class home in regular classes was a predictor of not having personality disorders. In contrast, being in the higher grades and from a lower socio-economic-status home in regular classes was a predictor of disruptive behavior.

Howard (1978), in a study of factors on school vandalism, concluded that the middle school or junior high school student is the age group within which most vandals have been found. He also pointed out that vandalism is almost exclusively a male activity, and there is a high correlation between delinquent students and educational deficiency. The study further indicated that many parents associate school discipline with the school principal.

Poorman, Donnerstein, and Donnerstein (1976) noted that males as opposed to females tend to engage in, as well as provoke, higher levels of aggressive behavior. Results of this study indicated that aggression between females was relatively stable over age. In contrast, aggression between males increased significantly. They suggested that this increase is the result of this kind of behavior being rewarded by peers and parents.

In a study designed to investigate the touch interactions between junior high school students, Willis and Reeves (1976) noted that females were observed to use fists and other aggressive touches, something that had not been observed in an earlier study. They concluded that "the increased aggressive touch may be a reflection of the increased aggression of young females that has been reported in recent years" (p. 91).

Rice (1975) expounded on the effects of task-focused and approval-focused discipline techniques. How is the

target of the discipline viewed by his observing peers?
Two variables were studied--sex and type of desist
(command). The scores of the personality-trait of the
student were studied as well as the personality-trait
rating of the teacher, the confidence in the rating
of the child and of the teacher. The students who
hastened to the task-focused desists differed signifi-
cantly in their responses on the measures from those who
heard the approval-focused desists. Neither the sex of
the rater nor the sex of the ratee and type of desist
interaction was significant (p 10). This seems to bear
upon the question, raised earlier, regarding the possi-
bility of sex as a significant predictor of disruptive
behavior.

Literature on School Location

In the Teacher Opinion Poll of the National
Education Association (1974), 5.4% of the sampled urban
secondary school personnel reported they had experienced
on-the-job physical assaults, while only 2.0% of the
sample's rural and suburban personnel said they had
similar experiences.

Koch (1975) found that the rate of teacher
assault and personal property damage has increased
dramatically in urban school districts.

Cloward and Ohlin (1960) considered delinquent behavior primarily centered upon lower class, urban, male adolescents. It is interesting to note the very real and pronounced difference existing between the incidence of disruptive behavior in lower class urban and lower class rural adolescents. The answers may be that the rural environment does not pose a threat of hostility to the low-income-family youth because he will not be likely to be confronted with and defeated by middle or upper class children in social, academic, and other achievement areas, but will be instead con-fronted with children of like backgrounds and similar likelihood of success levels.

Literature on School Size

Kelly (1978) suggested that observed physical conflict between students will increase as relative school population density increases. He further contended:

> The presence of such . . . student populations and a variety of recent professional and public observations concerning school violence, absen-teeism, and the decline of achievement standards suggests that some correspondence between these factors may indeed exist. . . . The current literature indicates that student conflict and corollary suspensions are far more prevalent in large urban secondary schools than in suburban or rural schools. . . . In its report on causes of student conflict in California's schools, the California State Department of Education cited school overcrowding as a major causal factor, noting that in schools where overcrowding is severe, the students report it is tiring to go to classes which are too large, to stand in lines to eat in the cafeteria or use the

restrooms and to line up to get a locker. The
attendant noise and fatigue (alone) provide a
climate for unrest. (pp. 152 & 156)

Baron (1975) studying the correspondence of
human overcrowding in living space to specific social
pathologies, reported public schools reflecting more
consistently adverse patterns of overcrowding.

The size and enrollment of the school has
been associated with discipline problems, violence,
and vandalism. Kingston and Gentry (1977) noted that
students in large high schools found it difficult to
identify with their schools and seldom participated
in school activities. The authors observed that this
may be the cause of disciplinary problems. In another
study, DeBuzna (1974) reported that the rate of
vandalism increased as the number of students enrolled
in the school increased.

The studies of The Teachers Task Force (1974)
indicated a negative relationship between school over-
crowding and academic achievement, while a study
conducted by Davis (1972) found that students in medium
to large size high schools (2,000-4,000) evidenced
lower grades than students in small size high schools.

Literature on the School Principal

Goldman (1961) indicated that teachers in schools
with high rates of vandalism described their principal

as weak and casual, while their counterparts in schools with low rates of vandalism characterized the principal as strong and democratic.

An article by Love (1977) contended that, in integrated schools, the failure to diagnose problems with accuracy originates in the inability of school administrators to view themselves in a new perspective. They cannot understand why their policies and teaching methodologies, effective in the past, no longer work, and they refuse to change because of an ideological barrier made up of concepts of differences; i.e.,

1. differences in their minds that translate into deficits for minority students

2. holding low expectations for the academic performance of minority children

3. using inappropriate materials

4. poor interpersonal relationships between teachers and minority students

5. biased counseling practices of teachers and principals as well as counselors

6. failure to relate to minority students as individuals

7. bias in the administration of discipline.

Love indicated what evidence to look for in order to ascertain if these behavior patterns existed in any

particular school. According to the article, illustrations
of biased administration of discipline are:

     1. To assume when there are behavior problems
that minority students started it or know something about
it.

     2. To punish a student who is not involved in
disruptive behavior for not telling all he knows

     3. Ignoring white students' misbehavior while
disciplining minority students for any rule infraction

     4. Using white cultural norms and values in the
administration of discipline

     5. Low rate of suspension and expulsion for
white students in contrast to high rate for their minority
counterparts, with a longer period of suspension for the
latter

     6. Higher rate of disciplinary action for minority
pupils as a result of subjective decisions by teachers
and administrators.

     Shuttlesworth and Evans (1974) stressed that "the
principal must always keep foremost in his mind that he
is the principal of all the students regardless of race, color,
or creed" (p. 50). To illustrate what can happen if the
principal fails to follow this, they pointed out that in
one high school of about 2,000 students, 80% white and 20%
black:

    . . . several white teachers sent far more black
    students than white students to the principal's
    office for disciplinary reasons. When the black

> students felt that the white principal was
> defending what they considered "racism" (which
> the principal might or might not have been doing),
> they began to polarize, using as a slogan: "We'd
> better start sticking together!" Polarization
> first began among those blacks who had been sent to
> the office, and rapidly spread to include almost all
> other black students. No race riot broke out, but
> hostility was strong and rumors of rioting lasted
> for weeks. (p. 50)

In implementing a group therapy program to help disruptive
students, Webster (1974) stressed the importance of
obtaining the support of the school principal for this
type of intervention to be accepted by the school in
general, its effectiveness and success.

Summary

This chapter has reviewed selected literature on
disruptive behavior; ethnicity, socio-economic status,
and sex as student variables, and location, size, and
the principal as school variables. Some of the research
literature reviewed in this chapter established the basis
for this present study.

Significant findings pertinent to this study
have been included in this chapter, i.e., relevant to
the student socio-economic status (Hollingshead, 1949;
Reissman, 1953; Coleman, 1966; Jencks, 1972; McPartland
and McDill, 1975), ethnicity (The Governor's Task Force
on Disruptive Youth, 1973; Walberg et al., 1974; Zirkel and
Gable, 1977), sex (Rice, 1975; Touliatos and Lindholm, 1976;

Howard, 1978). Further relevant findings, related to
school location were included, i.e. (The Teacher
Opinion Poll of the National Education Association,
1974; Koch, 1975), size (Baron, 1975; Kelly, 1978), and the
principal (Shuttlesworth and Evans, 1974; Love, 1977).
Furthermore, most of the reported research serves as
background from which perspectives can be established
in evaluating this study.

CHAPTER III

DESIGN OF THE STUDY

This study used a comparative survey method to
investigate the relationship between disruptive and non-
disruptive students in tri-ethnic junior high schools.
Three variables of student characteristics, socio-economic
class, ethnicity, and sex were tested in order to determine
whether they were predictors of disruptive behavior in tri-
ethnic junior high schools. Also three variables of
school characteristics, size, location, and ethnicity
of the principal, were tested in order to determine whether
they were factors in the incidence of disruptive behavior in
tri-ethnic junior high schools. The students variables were
tested by intergroup and intragroup comparison techniques
in order to determine whether disruptive junior high school
students can be predicted by any of the variables inde-
pendently or in any combination of the three. The school
variables were tested to determine whether the variables, as
a single unit, were predictive of disruptive behavior in the
junior high school. In addition, the previously mentioned
student variables were tested as to whether each together
with each of the school variables was predictive of
disruptive behavior in tri-ethnic junior high schools.

42

Hypotheses

Three variables concerning characteristics of junior high school students were identified. This study analyzed the interactions of these variables with each of the three variables concerning characteristics of tri-ethnic junior high schools.

The student variables were socio-economic status, ethnicity, and sex. The school variables were: size, location, and ethnic origin of the principal. The dependent variable in this study was disruptive behavior.

In order to test the interactions of the student and school variables, the following null hypotheses were formulated

H_1--There is no significant difference between the socio-economic position, the ethnicity, and the sex of the student, the location, the size, and the ethnic origin of the principal of the school, and the frequency of disruptive students.

H_2--There is no significant difference between the proportion of disruptive and non-disruptive students of different socio-economic positions.

H_3--There is no significant difference between the expected and observed proportions of disruptive and non-disruptive students of different ethnic origins.

H_4--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of different sexes.

H_5--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of lower socio-economic position and different ethnic origins.

H_6--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of middle-socio-economic position and different ethnic origins.

H_7--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of upper socio-economic position and different ethnic origins.

H_8--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students, male and female, of lower socio-economic position.

H_9--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students, male and female, of middle socio-economic position.

H_{10}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students, male and female, of upper socio-economic position.

H_{11}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive black American students of different sexes.

H_{12}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive white American students of different sexes.

H_{13}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive Hispanic-origin students of different sexes.

H_{14}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students in schools with principals of different ethnic origins.

H_{15}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of lower socio-economic position in schools with principals of different ethnic origins.

H_{16}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of middle socio-economic position in schools with principals of different ethnic origins.

H_{17}--There is no significant difference between
the expected and the observed proportions of disruptive
and non-disruptive students of upper socio-economic
position in schools with principals of different ethnic
origins.

H_{18}--There is no significant difference between
the expected and the observed proportions of disruptive
and non-disruptive black American students in schools
with principals of different ethnic origins.

H_{19}--There is no significant difference between
the expected and the observed proportions of disruptive
and non-disruptive white American students in schools
with principals of different ethnic origins.

H_{20}--There is no significant difference between
the expected and the observed proportions of disruptive
and non-disruptive Hispanic-origin students in schools
with principals of different ethnic origins.

H_{21}--There is no significant difference between
the expected and the observed proportions of disruptive
and non-disruptive male students in schools with
principals of different ethnic origins.

H_{22}--There is no significant difference between
the expected and the observed proportions of disruptive
and non-disruptive female students in schools with
principals of different ethnic origins.

H_{23}--There is no significant difference between
the expected and the observed proportions of disruptive

and non-disruptive students in schools of different sizes.

H_{24}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of lower socio-economic position in schools of different sizes.

H_{25}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of middle socio-economic position in schools of different sizes.

H_{26}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of higher socio-economic position in schools of different sizes.

H_{27}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive black American students in schools of different sizes.

H_{28}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive white American students in schools of different sizes.

H_{29}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive Hispanic-origin students in schools of different sizes.

H_{30}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive male students in schools of different sizes.

H_{31}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive female students in schools of different sizes.

H_{32}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students in urban and suburban schools.

H_{33}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of lower socio-economic position in urban and suburban schools.

H_{34}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of middle socio-economic position in urban and suburban schools.

H_{35}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of upper socio-economic position in urban and suburban schools.

H_{36}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive black American students in urban and suburban schools.

H_{37}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive white American students in urban and suburban schools.

H_{38}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive Hispanic origin students in urban and suburban schools.

H_{39}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive male students in urban and suburban schools.

H_{40}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive female students in urban and suburban schools.

H_{41}--There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students in different grades.

Procedures

Measures of socio-economic status, ethnicity, sex, and disruptive behavior of the students were obtained from information provided by selected tri-ethnic

junior high schools. The group of identified disruptive junior high school students was compared to the group of identified non-disruptive junior high school students on the three variables of socio-economic position, ethnicity, and sex. Measures of three variables of the school characteristics, size, location, and the ethnic origin of the principal were also obtained. The relationship between the six independent variables and the dependent variable was statistically tested. In addition, combinations of the six independent variables were statistically tested, as well as within group measures of all the independent variables. The subjects, the instruments, the method, and the statistical analyses utilized in this study will follow.

Subjects

There are 46 junior high schools in Dade County with over 61,000 students, with approximately equal numbers of males and females. Of these 46 junior high schools, 26 have a tri-ethnic student population in which each ethnic group has a representation of at least 6% of the total school population. The ethnic composition of the junior high school population is listed in Table No. 1.

Permission was obtained from the Dade County Schools Research Committee to conduct the study in selected

TABLE 1

ETHNICITY

Ethnicity	Students	Percentage
White Americans	24,199	39.30
Black Americans	15,879	25.79
Hispanic Origin	21,226	34.48
Other Minorities	265	0.43
Total	61,569	100.00

tri-ethnic junior high schools. Subjects were drawn from 12 junior high schools in Dade County with a total enrollment of 14,281 students. Half of the junior high schools were located in urban Dade County and the other half in suburban Dade County.

Of the 12 junior high schools selected for this study, 2 were of small size, 7 were of medium size, and 3 were of large size. Fifty percent (50%) of the junior high school principals were white American and the other 50% were non-white Americans.

A stratified random sample of 30 black American, 30 white American, and 30 Hispanic-origin students was selected from each of the 12 junior high schools. Half of the students in each ethnic group were male and the other half female. There was a total of 1,080 subjects

in this study. This represented approximately 1.75% of
the total junior high population and 7.6% of the enrollment
of the selected junior high schools in this study. Of the
students selected in the sample, 270 were in the 7th grade,
407 were in the 8th grade, 396 in the 9th grade, and 7
failed to indicate the grade. Only 120 were in the
upper socio-economic position, with 468 in the middle,
and 492 in the lower socio-economic positions. School
authorities identified 123 students as disruptive and
950 as non-disruptive. Most of them (630) attended
medium size schools, with 270 in large schools, and 180
in small schools.

TABLE 2

JUNIOR HIGH SCHOOL COMPLAINTS REPORTED TO THE DADE COUNTY
SCHOOLS SECURITY ENFORCEMENT DEPARTMENT
IN THE 1976/1977 SCHOOL YEAR

Offense	No of Complaints
Rape	1
Robbery	82
Assault	660
Theft	636
Arson	41
Vandalism	488
Possessing a weapon	48
Sex offense	22
Marijuana	91
Disorderly conduct	269
Total	2,338

School No. 1 (for the purposes of this study the schools will be identified, 1, 2, 3 . . . 12), large in size, with a white principal, located in suburban Dade County, had an enrollment of 1,520 7th, 8th, and 9th grade students. The ethnic composition of the school population was 20% black American, 72% white American, 7% Hispanic-origin, and 1% others. Approximately 13% of the students were determined to be economically disadvantaged.

School No. 2, small in size, with a non-white principal, located in urban Dade County, had an enrollment of 758 7th, 8th, and 9th grade students. The ethnic composition of the school population was 45% black American, 17% white American, and 37% Hispanic origin. Approximately 71% of the students were determined to be economically disadvantaged.

School No. 3, medium in size, with a white principal, located in suburban Dade County, had an enrollment of 1,431 7th, 8th, and 9th grade students. The ethnic composition of the school population was 42% black American, 17% white American, and 42% Hispanic origin. Approximately 60% of the students were determined to be economically disadvantaged.

School No. 4, small in size, with a non-white principal, located in urban Dade County, had an enrollment of 497 7th grade students. The ethnic composition

of the school population was 32% black American, 46% white American, and 22% Hispanic origin. Approximately 32% of the students were determined to be economically disadvantaged.

School No. 5, large in size, with a white principal, located in urban Dade County, had an enrollment of 1,570 7th, 8th, and 9th grade students. The ethnic composition of the school population was 26% black American, 6% white American, and 68% Hispanic origin. Approximately 69% of the students were determined to be economically disadvantaged.

School No. 6, large in size, with a white principal, located in suburban Dade County, had an enrollment of 1,644 7th, 8th, and 9th grade students. The ethnic composition of the school population was 20% black American, 7% white American, and 73% Hispanic origin. Approximately 48% of the students were determined to be economically disadvantaged.

School No. 7, medium in size, with a non-white principal, located in urban Dade County, had an enrollment of 1,204 7th, 8th, and 9th grade students. The ethnic composition of the school population was 65% black American, 16% white American, and 19% Hispanic origin. Approximately 64% of the students were determined to be economically disadvantaged.

School No. 8, medium in size, with a white principal, located in urban Dade County, had an enrollment of 1,291 7th, 8th, and 9th grade students. The ethnic composition of the school population was 51% black American, 29% white American, 19% Hispanic origin, and 1% other. Approximately 54% of the students were determined to be economically disadvantaged.

School No. 9, medium in size, with a non-white principal, located in suburban Dade County, had an enrollment of 1,380 7th, 8th, and 9th grade students. The ethnic composition of the school population was 16% black American, 73% white American, 10% Hispanic origin, and 1% other. Approximately 23% of the students were determined to be economically disadvantaged.

School No. 10, medium in size, with a white principal, located in urban Dade County, had an enroll- ment of 1,277 8th and 9th grade students. The ethnic composition of the school population was 40% black American, 37% white American, and 23% Hispanic origin. Approximately 23% of the students were determined to be economically disadvantaged.

School No. 11, medium in size, with a non-white principal, located in suburban Dade County, had an enrollment of 1,316 7th, 8th, and 9th grade students. The ethnic compo- sition of the school population was 37% black American, 46% white American, and 17% Hispanic origin. Approximately 34% of the students were determined to be economically disadvantaged.

School No. 12, medium in size, with a non-white principal, located in suburban Dade County, had an enrollment of 1,408 7th, 8th, and 9th grade students. The ethnic composition of the school population was 44% black American, 31% white American, 24% Hispanic origin, and 1% other. Approximately 57% of the students were determined to be economically disadvantaged.

There were 12,956 students suspended from Dade County junior high schools during the first three quinmesters of the 1977/78 school year. Eight hundred forty-three (843) of them were enrolled in the 12 junior high schools that participated in this study.

Instruments

In Chapter I, the questionnaire used to gather the data needed for this study was discussed. However, the information needed to determine the socio-economic position of the subjects had to be processed. The Two Factor Index of Social Position (Hollingshead, 1957) was used to compute an index of socio-economic class. The index was developed by Hollingshead to "meet the need for an objective, easily applicable procedure to estimate the position individuals occupy in the status structure of our society" (p. 235).

The two factors used in the index were the occupation and the educational level of the head of the

household.   The occupations are ranked in seven

categories.

> . . . (1) executives and proprietors of large
> concerns and major professionals; (2) managers and
> proprietors of medium concerns and minor
> professionals; (3) administrative personnel of large
> concerns, owners of small independent businesses, and
> semiprofessionals; (4) owners of little businesses,
> clerical and sales workers, and technicians; (5)
> skilled workers; (6) semiskilled workers; and
> (7) unskilled workers. (p. 235)

This scale is based on the premise that society gives

distinct values to different occupations because they

reflect the skill and power of individuals.   The educa-

tional scale is divided into seven levels:

> . . . (1) graduate professional training (persons
> who completed a recognized course which led
> to the receipt of a graduate degree); (2) standard
> college or university graduation (individuals who
> had completed a four-year college or university
> course leading to a recognized college degree);
> (3) partial college training (individuals who had
> completed at least one year but not a full college
> course); (4) high-school graduation (all secondary-
> school graduates, whether from a private preparatory
> school, public high school, trade school, or
> parochial high school); (5) partial high school
> (individuals who had completed the tenth or eleventh
> grades but not the high school course); (6) junior
> high school (individuals who had completed the
> seventh, eighth, or ninth grades); (7) less than
> seven years of school (individuals who had completed
> less than seven grades irrespective of the amount
> of education received.   (p. 236)

This scale is based on the premise that people with similar

education tend to have similar attitudes, tastes, and

behavior patterns.

In order to calculate the index of social posi-

tion, the value for occupation is multiplied by a factor

weight of seven. The value for education is multiplied
by a factor weight of four, and both products are
added. The scores range from a low of 11 to a high
of 77. In this study the scores were divided into three
levels.

TABLE 3

SCORES USED TO DETERMINE
SOCIO-ECONOMIC POSITION

Socio-Economic Position	Total Score
Lower	11-22
Middle	23-51
Upper	52-77

The questionnaire used in this study provided
information on the occupation and the education of
both parents. If information for both parents was
given, it was assumed that the father was the head of
the household. When the only information given in the
questionnaire was "unemployed" and no additional informa-
tion could be obtained, the student was assumed to be of
lower socio-economic status.

Methods

During the spring of 1978 permission to conduct
this study was requested from 14 junior high school

principals. Only one refused to give his authorization;
hence, because of the research design, it was also
necessary to eliminate a second school that had been
paired with it.

Questionnaires with the names of the students
selected for the study already written upon them were
delivered to the 12 junior high schools that had accepted
the invitation to participate in the study. A conference
was held with the assistant principal for guidance of
each school in order to ensure good cooperation and
better understanding of the study. It was requested that
the assistant principal randomly replace any subject no
longer in the school. The replacement would be chosen
with the same demographic characteristics.

The questionnaires were completed by the students
under the supervision of a guidance counselor. The
assistant principal in charge of discipline reviewed the
questionnaires once they had been completed by the
students in order to ascertain that Item No. 8 (Was the
student suspended ?) had been answered accurately.

Before being returned by the schools, the students'
names were detached from the questionnaires, because of
a requirement of the Dade County Schools Research
Committee designed to maintain the privacy rights of the
students. Furthermore, after receiving the questionnaires,
the names of the schools were also detached, in order to

comply with the request to maintain the names of the
schools which participated in this study in anonymity
and these were placed in envelopes labeled:

	1	2	3	4	5	6	7
Principal	Non/W	Non/W	Non/W	W	W	W	W
Size	M	S	M	L	M	M	L
Location	U	U	S	U	S	U	S

When all questionnaires were returned, the data
were coded and keypunched.

Statistical Analysis

Hypothesis 1 was tested in order to determine if
several student and school independent variables were
predictors of disruptive behavior. Multiple regression
was used in the statistical analysis. Kerlinger (1964)
pointed out:

> Multiple regression is close to the heart of
> scientific investigation. It is also fundamental
> in statistics and inference, and is tightly tied
> to basic and powerful mathematical methods. From the
> researcher's point of view, moreover, it is useful
> and practical: it does its analytic job successfully
> and efficiently. (p. 630)

Discussing this statistical technique as an inferential

tool, Nie et al. (1975) wrote:

> Through multiple regression techniques the
> researcher could obtain a prediction equation
> that indicates how scores on the independent
> variables could be weighted and summed to obtain
> the best prediction of the dependent variable. (p. 321)

Because of the nominal-scale nature of the six independent variables and the dichotomous nominal-scale nature of the dependent variable, "dummy" variables had to be used.

Hypotheses 2 through 41 were formulated to test intergroup and intragroup relationships. Chi square was used in the statistical analysis because it is a test of statistical significance that helps to determine if there is a systematic relationship between two variables.

Summary

The focus of this chapter was the design of this study. The hypotheses were formulated, the procedures were explained, the subjects as well as the instruments were described, and the methods used in the statistical analysis were outlined. The methods of sampling and data collection were previously discussed in Chapter I. An analysis of the results is discussed in Chapter IV.

CHAPTER IV

RESULTS

The major purpose of the present study was to
ascertain if there was a relationship among certain
student characteristics, certain school characteristics,
and disruptive behavior. Three independent variables of
student characteristics and three independent variables
of school characteristics were combined to formulate
39 null hypotheses. Because the information was avail-
able, a fourth independent variable of student character-
istics, school grade, was used by itself in formulating
one null hypothesis and in combination with the other
independent variables for a total of 41 null hypotheses.

Two statistical techniques were used to analyze
the data in this study. The forward (stepwise) inclusion
approach of multiple linear regression was used in testing
the first hypothesis for predictability. Chi square was
used to test the rest of the hypotheses for relationship.

The findings of this study are grouped into six
sections. Section I presents the findings of testing
hypothesis one, which tries to determine whether any of the
independent variables or any combination of them are
predictors of disruptive behavior. Section II presents

62

the results of testing the independent variables of

socio-economic position, ethnicity, and sex of the

students formulated in hypotheses 2, 3, 4, 5, 6, 7, 8,

9, 10, 11, 12, and 13. Section III presents the results

of testing the independent variable of the ethnicity of

the principal and its relationship with students'

variables formulated in hypotheses 14, 15, 16, 17, 18,

19, 20, 21, and 22. Section IV presents the results

of testing the independent variable of the size of the

school and its relationship with student variables

formulated in hypotheses 23, 24, 25, 26, 27, 28, 29,

30, and 31. Section V presents the results of testing

the independent variable of the location of the school

and its relationship with student variables formulated on

hypotheses 32, 33, 34, 35, 36, 37, 38, 39, and 40.

Section VI presents the results of testing the independent

variable of the students' grade placement.

Section I

      H_1, There is no significant difference between
the socio-economic position, the ethnicity, the grade,
and the sex of the student; the location, the size,
and the ethnic origin of the principal of the
school and the frequency of disruptive students.

Multiple regression was run to determine whether the independent

variables were predictors of disruptive behavior. The equa-

tion used in this statistical technique was:

$$Y = C + B_1X_1 + B_2X_2 + \ldots + B_KX_K$$

The best predictors obtained in the regression analysis were (1) socio-economic position--lower; (2) sex-- male; (3) ethnicity--non-Hispanic; (4) grade--non-eighth grader.

The values obtained in the regression analysis produced the following equation:

$$Y = 0.02788 + .18075X_1 + .8506X_2$$

$$- .6398X_3 - .4653X_4$$

where Y is the predicted dependent variable, X_1 lower socio-economic position, X_2 male, H_3 Hispanic origin, and X_4 eighth grade.

The results of the analysis of variance in each step of the multiple regression showed the variables listed in Table 4 significant at the 0.01 level.

TABLE 4

RESULTS OF STEPWISE MULTIPLE REGRESSION ANALYSIS AND
RESULTS OF THE ANALYSIS OF VARIANCE IN THE
MULTIPLE REGRESSION

Variable	B	Beta	Standard Error B
Lower socio-economic position	.18075	.28336	0.01872
Male	.8506	.13388	0.01840
Hispanic	-.6398	-.09495	0.01976
Grade 8	-.4653	-.07098	0.01900

TABLE 4 (continued)

Variable	Degrees of Freedom	F
1. Lower socio-economic position	1	84.1045
2. Male sex	2	54.49337
3. Hispanic ethnic origin	3	39.89209
4. Eighth grade	4	31.55811

Since the null hypothesis encompassed all the independent variables, it is not rejected. However, it can be said that the student with most probability of being suspended is of lower socio-economic position, male, not of Hispanic origin nor in the eighth grade.

Section II

Chi square was used to test the statistical significance of the rest of the hypotheses in this study. It determines whether a relationship exists between two variables. The following formula was used in this statistical technique:

$$\chi^2 = \sum_i \frac{\left(f_o^i - f_e^i\right)^2}{f_e^i}$$

where f_o^i is the observed frequency in each cell and f_e^i is the expected frequency.

The hypotheses in this section test the relationship between disruptive behavior and the socio-economic status, ethnicity, and sex of the student.

H_2, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of different socio-economic positions.

TABLE 5

DISRUPTIVE AND NON-DISRUPTIVE STUDENTS OF
DIFFERENT SOCIO-ECONOMIC POSITIONS

		Lower	Middle	Upper	Row Total
Non-	Count	390	448	119	957
Disruptive	Row Pct.	40.8	46.8	12.4	88.6
	Col. Pct.	79.3	95.7	99.2	
	Tot. Pct.	36.1	41.5	11.0	
Disruptive	Count	102	20	1	123
	Row Pct.	82.9	16.3	0.8	11.4
	Col. Pct.	20.7	4.3	0.8	
	Tot. Pct.	9.4	1.9	0.1	
Total Column		492	468	120	1080
Total Column Pct.		45.6	43.3	11.1	100.0

Chi square was run to determine any statistical relationship between disruptive behavior and students' socio-economic position. The obtained chi square of 79.28 with 2 degrees of freedom had a probability of less than 0.0001. Therefore,

the null hypothesis is rejected. In order to determine
which of the proportions of lower, middle, and upper
socio-economic position was statistically significant,
the z test formula for significance of difference
between proportions (Glass and Stanley 1970, p. 325) was
used.

$$z = \frac{P_1 - P_2}{\sqrt{\left(\dfrac{f_1 + f_2}{n_1 + n_2}\right)\left(1 - \dfrac{f_1 + f_2}{n_1 + n_2}\right)\left(\dfrac{1}{n_1} + \dfrac{1}{n_2}\right)}}$$

The proportions of disruptive and non-disruptive
students of middle and upper socio-economic position ob-
tained a z value of 1.88, not high enough to be
significant at the .05 level.

There was a statistically significant difference
at the 0.01 level between the proportion of disruptive
students of lower socio-economic position and the pro-
portions of disruptive students of middle and upper
socio-economic positions.

H_3, There is no significant difference between
the expected and the observed proportions of
disruptive and non-disruptive students of different
ethnic origins.

Chi square was run to determine any statistical
relationship between the incidence of disruptive behavior
and the ethnicity of the students. The obtained chi
square of 13.59 with 2 degrees of freedom had a probability
of .0011. Therefore, the null hypothesis is rejected. The

TABLE 6

students of different sex. The obtained chi square of
22.94 with 1 degree of freedom had a probability of
less than 0.0001. Of the students identified as dis-
ruptive 87 were male and 36 female. Therefore, the null
hypothesis is rejected.

H_5, There is no significant difference between
the expected and the observed proportions of dis-
ruptive and non-disruptive students of lower socio-
economic position and different ethnic origins.

Chi square was run to determine any statistical
relationship between disruptive and non-disruptive
students of lower socio-economic position and different

ethnic origins. The obtained chi square of 8.97 with 2
degrees of freedom had a probability of 0.0113. Therefore,
the null hypothesis is rejected. The proportions of black
American and white American disruptive and non-disruptive
students obtained a z value of 0.46, which is not
statistically significant. There was a statistically
significant difference at the 0.01 level between the
proportions of disruptive and non-disruptive black American
students and the proportions of disruptive and non-
disruptive Hispanic-origin students. A high z value of 1.85
was obtained between the proportion of disruptive and

non-disruptive white American students and disruptive and

non-disruptive Hispanic-origin students, but it failed

to reach the value of 1.96 needed to be significant at

the 0.05 level.

H_6, There is no significant difference between
the expected and the observed proportions of
disruptive and non-disruptive students of middle
socio-economic position and different ethnic
origins.

TABLE 9

DISRUPTIVE AND NON-DISRUPTIVE STUDENTS OF MIDDLE
SOCIO-ECONOMIC POSITION BY ETHNICITY

Total Column		27	27	66	120
Total Column Pct.		22.5	22.5	55.0	100.0

Chi square was run to determine any statistical relationship between disruptive and non-disruptive students of upper socio-economic position and different ethnic origins. The obtained chi square of 3.47 with 2 degrees of freedom had a probability of 0.176. Therefore, the null hypothesis is not rejected. Only one student

in this socio-economic status was identified as
disruptive, which represents 0.8% of the total number
of students in this group. Since one of the require-
ments of chi square, that the expected value of any
cell never be less than 5, is not met, a z test was conducted
with the following not statistically significant results:

Black Americans and white Americans z = 1.57

Black Americans and Hispanic-origin students

z = 1.008

H_3, There is no significant difference between
the expected and the observed proportions of
disruptive and non-disruptive students, male and
female, of lower socio-economic position.

TABLE 11

DISRUPTIVE AND NON-DISRUPTIVE STUDENTS OF LOWER
SOCIO-ECONOMIC POSITION BY SEX

Total Column Pct.		47.5	52.5	100.0

Chi square was run to determine any statistical
relationship between disruptive and non-disruptive students

of upper socio-economic position and different sexes.
The obtained chi square of 0.003 with 1 degree of
freedom had a probability of 0.96. Therefore, the null
hypothesis is not rejected. As was stated before, only
1 student was identified as disruptive in this socio-
economic position. Since the chi square requirement,
that the expected value of any cell never be less than
5, is not met, a z test was conducted. The value of 1.08
was not statistically significant.

H_{11}, There is no significant difference between
the expected and the observed proportions of
disruptive and non-disruptive black American students
of different sexes.

TABLE 14

	Tot. Pct.	5.6	2.8	
Total Column		180	180	360
Total Column Pct.		50.0	50.0	100.0

Chi square was run to determine any statistical relationship between disruptive and non-disruptive white American students of different sexes. The obtained chi square of 2.945 with 1 degree of freedom had a probability of 0.0861. Although 11.9% of the males, in contrast to 4.4% of the females in this group were identified as disruptive, the null hypothesis is not rejected.

H_{13}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive Hispanic-origin students of different sexes.

TABLE 16

DISRUPTIVE AND NON-DISRUPTIVE HISPANIC-ORIGIN STUDENTS
BY SEX

		Male	Female	Row Total

Disruptive	Count	24	10	34
	Row Pct.	70.6	29.4	9.4
	Col. Pct.	13.3	5.6	
	Tot. Pct.	6.7	2.8	
Total Column		180	180	360
Total Column Pct.		50.0	50.0	100.0

Chi square was run to determine any statistical
relationship between disruptive and non-disruptive
Hispanic-origin students of different sexes. The obtained
chi square of 5.49 with 1 degree of freedom had a
probability of 0.0191. Therefore, the null hypothesis
is rejected. Only 10 female Hispanic-origin students
were identified as disruptive in contrast to 24 males
in this group.

Section III

Hypothesis 14 tests the incidence of disruptive
behavior in schools with principals of different ethnic
origins. The rest of the hypotheses in this section
test this school variable with each of the student
variables.

H_{14}, There is no significant difference
between the expected and the observed proportions
of disruptive and non-disruptive students in
schools with principals of different ethnic origins.

Chi square was run to determine any statistical
relationship between the incidence of disruptive behavior
in schools with principals of different ethnic origins.
The obtained chi square of 0.147 with 1 degree of
freedom had a probability of 0.7016. Hence, the null
hypothesis is not rejected.

H_{15}, There is no significant difference between
the expected and the observed proportions of dis-
ruptive and non-disruptive students of lower socio-
economic position in schools with principals of
different ethnic origins.

Total Column		233	259	492
Total Column Pct.		47.4	52.6	100.0

Chi square was run to determine any statistical relationship between disruptive and non-disruptive lower socio-economic position students in schools with principals of different ethnic origins. The obtained chi square of 4.195 with 1 degree of freedom had a probability of 0.0406. Hence, the null hypothesis is rejected. Of the students identified as disruptive in this socio-economic position, 24.9% of the sample attended schools with white principals and 17% of the sample attended schools with principals of other ethnic origins.

H_{16}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of middle socio-economic position in schools with principals of different ethnic origins.

	Tot. Pct.	1.3	3.0	
Total Column		243	225	468
Total Column Pct.		51.9	48.1	100.0

Chi square was run to determine any statistical relationship between disruptive and non-disruptive middle socio-economic position students in schools with principals of different ethnic origins. The obtained chi square of 3.157 with 1 degree of freedom had a probability of 0.0756. Of the middle socio-economic status students attending schools with non-white American principals, 6.2% were identified as disruptive in contrast to 2.5% of the students in this group attending schools with white American principals. Hence, the null hypothesis is not rejected.

H_{17}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of upper socio-economic position in schools with principals of different ethnic origins.

Chi square was run to determine any statistical relationship between disruptive and non-disruptive upper socio-economic position students in schools with principals of different ethnic origins. Since, as previously pointed out, only one student was identified as disruptive in this socio-economic position, the obtained chi square of 0.0045 with 1 degree of freedom had a probability of 0.9465, and the null hypothesis is not rejected. A z test was made because the expected value of each cell was not 5 or above. The z of 1.082 was not statistically significant.

white American principals, only 22 were identified in

schools with non-white-American principals.

H_{19}, There is no significant difference between
the expected and the observed proportions of
disruptive and non-disruptive white American
students in schools with principals of different
ethnic origins.

Chi square was run to determine any statistical

relationship between disruptive and non-disruptive

white American students in schools with principals of

different ethnic origins. The obtained chi square of 8.18

with 1 degree of freedom had a probability of 0.0042.

TABLE 22

Chi square was run to determine any statistical relationship between disruptive and non-disruptive female students in schools with principals of different ethnic origins. The obtained chi square of 1.458 with 1 degree of freedom had a probability of 0.227. Hence, the null hypothesis is not rejected.

Section IV

Hypothesis 23 tests the incidence of disruptive behavior in schools of different sizes. The rest of the hypotheses in this section test this school variable with each of the student variables.

H_{23}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students in schools of different sizes.

TABLE 26

DISRUPTIVE AND NON-DISRUPTIVE STUDENTS
IN SCHOOLS OF DIFFERENT SIZES

Total Column		71	279	118	468
Total Column Pct.		15.2	59.6	25.2	100.0

Chi square was run to determine any statistical relationship between disruptive and non-disruptive students of middle socio-economic position in schools of different sizes.   The obtained chi square of 3.967 with 2 degrees of freedom had a probability of 0.1376.   Hence,

the null hypothesis is not rejected. The small size
schools with 15.2% of the sample's students in middle
socio-economic position, identified 30% of the disruptive
students in this group. Because the expected value of each
cell was not 5 or above, a z test was made. The obtained
value between the proportions of disruptive and non-
disruptive small and large school students was 1.876.
The obtained z between the proportions of small and
medium school students was 1.61. Both failed to be
significant at the .05 level.

H_{26}, There is no significant difference between
the expected and the observed proportions of
disruptive and non-disruptive students of upper
socio-economic position in schools of different sizes.

TABLE 29

DISRUPTIVE AND NON-DISRUPTIVE UPPER SOCIO-ECONOMIC
POSITION STUDENTS BY SIZE OF SCHOOL

		Small	Medium	Large	Row Total

Total Column		25	67	28	120
Total Column Pct.		20.8	55.8	23.3	100.0

Chi square was run to determine any statistical relationship between disruptive and non-disruptive students of upper socio-economic position in schools of different sizes. The obtained chi square of 0.798 with 2 degrees of freedom had a probability of 0.6711. Therefore, the null hypothesis is not rejected. A z test was made because the expected value of the disruptive students' cells was less than 5, with the following results:

Medium and large schools - z = 0.653

Medium and small schools - z = 0.617

None of these values is significant.

H_{27}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive black American students in schools of different sizes.

TABLE 30

Total Column Pct.		16.7	58.3	25.0	100.0

Chi square was run to determine any statistical relationship between disruptive and non-disruptive white

American students in schools of different sizes. The
obtained chi square of 8.031 with 2 degrees of freedom
had a probability of 0.018. Hence, the null hypothesis
is rejected. The proportions of disruptive and non-
disruptive white American students in small and
large schools obtained a z value of 2.95 which is
statistically significant at the 0.01 level. The z
value obtained of 2.12 in medium and large schools is
statistically significant at the 0.05 level.

H_{29}, There is no significant difference between
the expected and the observed proportions of
disruptive and non-disruptive Hispanic-origin
students in schools of different sizes.

Chi square was run to determine any statistical
relationship between disruptive and non-disruptive male

students in schools of different sizes. The obtained

chi square of 5.299 with 2 degrees of freedom had a

probability of 0.0707. Hence, the null hypothesis is

not rejected. The large size schools with 25% of the male

students, identified 18.4% as disruptive, while the

small size schools with 16.7% of the students in this

group identified 24.1%.

H_{31}, There is no significant difference between
the expected and the observed proportions of
disruptive and non-disruptive female students in
schools of different sizes.

TABLE 34

Total Column		90	315	135	540
Total Column Pct.		16.7	58.3	25.0	100.0

Chi square was run to determine any statistical

relationship between disruptive and non-disruptive female

students in schools of different sizes. The obtained

chi square of 3.98 with 2 degrees of freedom had a

probability of 0.1367. Hence, the null hypothesis is

not rejected. The large size schools with 25% of the

female students identified 33.3% as disruptive. The

small size schools with 16.7% of the students in this

group reported 5.6% as disruptive.

Section V

Hypothesis 32 tests the incidence of disruptive

behavior in urban and suburban schools. The rest of

the hypotheses in this section test the relationship

between this school variable and each of the student

variables.

H_{32}, There is no significant difference between
the expected and observed proportions of disruptive
and non-disruptive students in urban and suburban
schools.

Chi square was run to determine any statistical

relationship between the incidence of disruptive

behavior and the location of the school. The obtained

chi square of 0.0367 with 1 degree of freedom had a

probability of 0.8481. Hence, the null hypothesis is

not rejected.

H_{33}, There is no significant difference between
the expected and observed proportions of disruptive
and non-disruptive students of lower socio-economic
position in urban and suburban schools.

	Tot. Pct.	10.4	10.4	
Total Column		275	217	492
Total Column Pct.		55.9	44.1	100.0

Chi square was run to determine any statistical relationship between disruptive and non-disruptive lower socio-economic position students in urban and suburban schools. The obtained chi square of 1.524 with 1 degree of freedom had a probability of 0.217. Hence, the null hypothesis is not rejected. The suburban schools reported 23.5% of the sample as disruptive in contrast with 18.5% in the urban schools.

H_{34}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive students of middle socio-economic position in urban and suburban schools.

TABLE 37

DISRUPTIVE AND NON-DISRUPTIVE MIDDLE SOCIO-ECONOMIC POSITION STUDENTS BY SCHOOL LOCATION

		Urban	Suburban	Row Total

Total Column Pct.		42.9	57.1	100.0

Chi square was run to determine any statistical
relationship between disruptive and non-disruptive middle
socio-economic position students in urban and suburban
schools.   The obtained chi square was 0.0017 with 1 degree
of freedom and a probability of 0.9669.   The null
hypothesis, therefore, is not rejected.

H_{35}, There is no significant difference between
the expected and observed proportions of disruptive
and non-disruptive students of upper socio-economic
position in urban and suburban schools.

TABLE 38

DISRUPTIVE AND NON-DISRUPTIVE UPPER SOCIO-ECONOMIC
POSITION STUDENTS BY SCHOOL LOCATION

Total Column Pct.		53.3	46.7	100.0

Chi square was run to determine any statistical
relationship between disruptive and non-disruptive upper

socio-economic position students in urban and suburban

schools. The obtained chi square of 0.0045 with 1

degree of freedom had a probability of 0.9465. Hence,

the null hypothesis is not rejected. Because the

expected value of each cell was not 5 or above, a z

test was made. The obtained value of 1.082 is not

statistically significant.

H_{36}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive black American students in urban and suburban schools.

Chi square was run to determine any statistical

relationship between disruptive and non-disruptive black

American students in urban and suburban schools. The

obtained chi square of 0.324 with 1 degree of freedom

had a probability of 0.569. Therefore, the null

hypothesis is not rejected.

H_{37}, There is no significant difference between
the expected and observed proportions of disruptive
and non-disruptive white American students in
urban and suburban schools.

Total Column Pct.		50.0	50.0	100.0

Chi square was run to determine any statistical relationship between disruptive and non-disruptive male students in urban and suburb an schools. The obtained chi square of 1.37 with 1 degree of freedom had a probability of 0.2418. Hence, the null hypothesis is not rejected. Urban schools identified 49 male students as disruptive while suburban schools only identified 38.

H_{40}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive female students in urban and suburban schools.

TABLE 43

DISRUPTIVE AND NON-DISRUPTIVE FEMALE STUDENTS
BY SCHOOL LOCATION

		Urban	Suburban	Row Total

Total Column		270	270	540
Total Column Pct.		50.0	50.0	100.0

Chi square was run to determine any statistical relationship between disruptive and non-disruptive female students in urban and suburban schools. The obtained chi square of 5.0298 with 1 degree of freedom had a probability of 0.0249. Hence, the null hypothesis is rejected. Only 11 female students were identified as disruptive in urban schools; in contrast, suburban schools reported 25.

Section VI

Hypothesis 41 tests the incidence of disruptive behavior in the seventh, eighth, and ninth grades.

H_{41}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students in different grades.

TABLE 44

DISRUPTIVE AND NON-DISRUPTIVE STUDENTS IN SEVENTH, EIGHTH, AND NINTH GRADES

		Seventh Grade	Eighth Grade	Ninth Grade	Row Total

Total Column		270	407	396	1073
Total Column Pct.		25.2	37.9	36.9	100.0

Chi square was run to determine any statistical relationship between the incidence of disruptive behavior and the student's grade. The obtained chi square of 6.128 with 2 degrees of freedom had a probability of 0.0467. Hence, the null hypothesis is rejected. The

proportions of disruptive and non-disruptive ninth and
seventh grade students obtained a z value of 0.824; a z value
of 1.41 was obtained for seventh and eight grade students.
There was a statistically significant difference at the
0.05 level between the proportions of ninth and eighth
grade students with a z value of 2.47.

TABLE 45

COMPARISON OF DISRUPTIVE AND NON-DISRUPTIVE
EIGHTH GRADERS AND SEVENTH AND NINTH
GRADERS COMBINED

	Eighth Grade	Seventh & Ninth Grades	
Non-Disruptive	372	578	
Col. Pct.	91.4	86.8	
Disruptive	35	88	
Col. Pct.	8.6	13.2	
Total	407	666	1073

The proportions of disruptive and non-disruptive
eighth grade students and the proportions of seventh and
ninth grade students combined (See Table 45) obtained a
z value of 2.3 which is statistically significant at the
0.05 level. Seven questionnaires did not have grade
information.

Summary

In this chapter the results of the statistical analysis of all the hypotheses formulated in this study have been reviewed.

In Section I where the relationship of all the independent variables and the frequency of disruptive students were tested by multiple regression statistical technique in order to determine predictability, the null hypothesis was not rejected. However, an analysis of variance was made obtaining statistically significant fs at the 0.01 level for lower socio-economic status, male sex, Hispanic ethnic origin and eighth grade placement.

In Section II, where the relationship between disruptive behavior and the ethnicity, the socio-economic status and the sex of the students were tested, statistically significant differences were found in hypotheses 2, 3, 4, 5, 8, 11, and 13. The incidence of disruptive behavior in schools with principals of different ethnic origins and the relationships between this school variable and each of the student variables were tested in Section III. Statistically significant differences were found in hypotheses 15, 18, and 19. In Section IV, the incidence of disruptive behavior in schools of different sizes was tested. This section

also tested the relationships between this school variable and each of the student variables. A statistically significant difference was found in hypothesis 28. The incidence of disruptive behavior in urban and suburban schools and the relationships between this school variable and each of the student variables were tested in Section V. A statistically significant difference was found in hypothesis 40. Hypothesis 41, the only one tested in Section VI, found a statistically significant difference in the incidence of disruptive behavior of seventh, eighth, and ninth grade students. The summary, discussion, and conclusions of this study are presented in Chapter V.

CHAPTER V

SUMMARY, DISCUSSIONS, AND CONCLUSIONS

Summary

The purpose of this study was to examine the relationship between the socio-economic status, the ethnicity, and the sex of the student, the location and the size of the school, and the incidence of disruptive behavior at the junior high school level. A secondary purpose was to discover whether there is a relationship between the ethnicity of the school principal and the kinds of students who exhibit disruptive behavior.

Forty-one null hypotheses were tested:

H_1, There is no significant difference between the socio-economic position, the ethnicity, the grade, and the sex of the student; the location, the size, and the ethnic origin of the principal of the school and the frequency of disruptive students.

H_2, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of different socio-economic positions.

H_3, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of different ethnic origins.

H_4, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of different sexes.

110

H_5, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of lower socio-economic position and different ethnic origins.

H_6, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of middle socio-economic position and different ethnic origins.

H_7, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of upper socio-economic position and different ethnic origins.

H_8, There is no significant difference between the expected and the observed proportion of disruptive and non-disruptive students, male and female, of lower socio-economic position.

H_9, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students, male and female, of middle socio-economic position.

H_{10}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students, male and female, of upper socio-economic position.

H_{11}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive black American students of different sexes.

H_{12}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive white American students of different sexes.

H_{13}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive Hispanic-origin students of different sexes.

H_{14}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students in schools with principals of different ethnic origins.

H_{15}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of lower socio-economic position in schools with principals of different ethnic origins.

H_{16}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of middle socio-economic position in schools with principals of different ethnic origins.

H_{17}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of upper socio-economic position in schools with principals of different ethnic origins.

H_{18}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive black American students in schools with principals of different ethnic origins.

H_{19}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive white American students in schools with principals of different ethnic origins.

H_{20}, There is no significant difference between the expected and observed proportions of non-disruptive Hispanic-origin students in schools with principals of different ethnic origins.

H_{21}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive male students in schools with principals of different ethnic origins.

H_{22}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive female students in schools with principals of different ethnic origins.

H_{23}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students in schools of different sizes.

H_{24}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of lower socio-economic position in schools of different sizes.

H_{25}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of middle socio-economic position in schools of different sizes.

H_{26}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive students of upper socio-economic position in schools of different sizes.

H_{27}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive black American students in schools of different sizes.

H_{28}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive white American students in schools of different sizes.

H_{29}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive Hispanic-origin students in schools of different sizes.

H_{30}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive male students in schools of different sizes.

H_{31}, There is no significant difference between the expected and the observed proportions of disruptive and non-disruptive female students in schools of different sizes.

H_{32}, There is no significiant difference between the expected and observed proportions of disruptive and non-disruptive students in urban and suburban schools.

H_{33}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive students of lower socio-economic position in urban and suburban schools.

H_{34}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive students of middle socio-economic position in urban and suburban schools.

H_{35}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive students of upper socio-economic position in urban and suburban schools.

H_{36}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive black American students in urban and suburban schools.

H_{37}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive white American students in urban and suburban schools.

H_{38}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive Hispanic-origin students in urban and suburban schools.

H_{39}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive male students in urban and suburban schools.

H_{40}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive female students in urban and suburban schools.

H_{41}, There is no significant difference between the expected and observed proportions of disruptive and non-disruptive students in different grades.

The stratified random sample for this study was drawn from 12 junior high schools in Dade County with a student population of 14,281. A sample of 90 students was selected from each school. It contained equal numbers of males and females of each of the 3 ethnic groups. The school system had 46 junior high schools with an enroll-ment of 61,569. Of the 12 junior high schools selected for this study, 6 were located in the urban area of the

county and the rest in the suburban area. Half of the
schools had white American principals and the other
half had principals of different ethnic origins. Two of
the schools were of small size, 7 of medium size, and
3 of large size.

A questionnaire was used to gather the data for
this study. During the Spring of 1978, the students
completed the questionnaire under the supervision of
a guidance counselor. The assistant principal in charge
of discipline reviewed them once they had been completed
in order to ascertain that the information of whether the
student had been disruptive during the school year was
accurate. Of the 1080 students selected for this study,
123 were identified as disruptive. The Two Factor Index
of Social Position (Hollingshead, 1957) was used in order
to determine the socio-economic status of each student.

A forward (stepwise) inclusion approach of
multiple linear regression was used in testing the first
hypothesis to determine whether all the independent variables
(the student's socio-economic status, ethnicity, grade place-
ment, and sex; the location, size, and ethnic origin of the
principal of the school), were collectively predictors of
disruptive behavior. The values obtained in the regression
analysis were not statistically significant. Hence the null
hypothesis was not rejected. However, the results of the
analysis of variance in each step of the multiple regression

showed lower socio-economic status, male sex, Hispanic
origin and eighth grade with f values significant at the
0.01 level.

Chi square was used to test the rest of the
hypotheses in this study for statistical significance.

In testing the second null hypothesis to
determine the relationship between disruptive behavior
and students' socio-economic status, a chi square of
79.28, significant at the 0.01 level, was obtained.
Therefore, the null hypothesis was rejected. A z test
was run to determine which of the proportions of the
socio-economic status (lower, middle, upper) was statistically
significant. Lower socio-economic status resulted sig-
ificant at the 0.01 level.

In testing the third null hypothesis to determine
the relationship between the incidence of disruptive
behavior and the ethnicity of the student, a chi square
of 13.59, significant at the 0.01 level was obtained.
Hence, the null hypothesis was rejected. A significant
z value at the 0.01 resulted when the proportions of black
American students and the proportions of white American
and Hispanic-origin students were compared.

In testing the fourth null hypothesis for statisti-
cal relationship between the incidence of disruptive be-
havior and the sex of the student, a significant chi square
value of 22.94 was obtained, with male students being more

disruptive.   Therefore, the null hypothesis was rejected.

The fifth, sixth, and seventh null hypotheses tested the statistical relationships between the proportions of disruptive and non-disruptive lower, middle, and upper socio-economic status students, respectively, and their ethnic origin.   A significant chi square value of 8.97 was obtained among the proportions of lower socio-economic status black American, white American, and Hispanic-origin students.   A significant z value resulted between the proportions of disruptive and non-disruptive lower socio-economic status Hispanic-origin students and their black American and white American counterparts. Hence the fifth null hypothesis was rejected.   No statistically significant differences were obtained between the proportions of disruptive and non-disruptive middle and upper socio-economic status students of different ethnic origins.   Therefore, the sixth and seventh null hypotheses were not rejected.

The eighth, ninth, and tenth null hypotheses tested the relationship between the proportions of disruptive and non-disruptive male and female students of different socio-economic status.   A significant chi square value of 19.1 was obtained between the proportions of male and female students of lower socio-economic status, males being more disruptive.   Therefore, the eighth null hypothesis was rejected.   No statistically significant differences

were obtained between the proportions of male and female
students of middle and upper socio-economic status.
Hence, the ninth and tenth null hypotheses were not
rejected.

The eleventh, twelfth, and thirteenth null
hypotheses tested the relationship between the propor-
tions of disruptive and non-disruptive male and female
students of different ethnic origins. A significant
chi square value of 13.7 was obtained between the
proportions of male and female black American students,
with males being more disruptive. Therefore, the eleventh
null hypothesis was rejected. No statistically signifi-
cant difference was obtained between the proportions of
male and female white American students. Hence, the
twelfth null hypothesis was not rejected. A significant
chi square value of 5.49 was obtained between the pro-
portions of male and female Hispanic-origin students with
males being more disruptive. Therefore the thirteenth null
hypothesis was rejected.

In testing the fourteenth null hypothesis to deter
mine any statistical relationship between the incidence of
disruptive behavior in schools with principals of different
ethnic origins, a non-significant chi square value of 0.147
was obtained. Hence, the fourteenth null hypothesis was
not rejected.

The fifteenth, sixteenth, and seventeenth null
hypotheses tested the relationship between the proportions
of disruptive and non-disruptive lower, middle, and upper
socio-economic status students in schools with principals
of different ethnic origins. A significant chi square value
of 4.195 was obtained between the proportions of lower
socio-economic students, the schools with white American
principals identifying more disruptive students. There-
fore, the fifteenth null hypothesis was rejected. Non-
significant chi square values were obtained in testing the
proportions of middle and upper socio-economic status
students. Hence, the sixteenth and seventeenth null
hypotheses were not rejected.

The eighteenth, nineteenth, and twentieth null
hypotheses tested the relationship between the propor-
tions of disruptive and non-disruptive black American,
white American and Hispanic-origin students in schools
with principals of different ethnic origins. A significant
chi square value of 3.97 was obtained between the propor-
tions of black American students, the schools with white
American principals identifying more disruptive students.
Therefore the eighteenth null hypothesis was rejected. A
significant chi square value of 8.18 was obtained between
the proportions of white American students, the schools with
non-white American principals identifying more disruptive
students in this ethnic group. Hence, the nineteenth null
hypothesis was rejected. No significant differences were

obtained between the proportions of Hispanic-origin students. Therefore, the twentieth null hypothesis was not rejected.

The twenty-first and twenty-second null hypotheses tested the relationship between the proportions of disruptive and non-disruptive male and female students, respectively, in schools with principals of different ethnic origins. The chi square values obtained were not significant. Hence, the twenty-first and twenty-second null hypotheses were not rejected.

In testing the twenty-third null hypothesis to determine the statistical relationship between the incidence of disruptive behavior in schools of different sizes, a non-significant chi square value of 0.623 was obtained. Therefore, the twenty-third null hypothesis was not rejected.

The twenty-fourth, twenty-fifth, and twenty-sixth null hypotheses tested the relationship between the proportions of disruptive and non-disruptive lower, middle, and upper socio-economic-status students, respectively, in schools of different sizes. Non-significant chi square values were obtained. Hence, the twenty-fourth, twenty-fifth, and twenty-sixth null hypotheses were not rejected.

The twenty-seventh, twenty-eighth, and twenty-ninth null hypotheses tested the relationship between the proportions of disruptive and non-disruptive black American, white American and Hispanic-origin students,

respectively, in schools of different sizes. A non-significant chi square value of 0.501 was obtained between the proportions of black American students. Therefore, the twenty-seventh null hypothesis was not rejected. A significant chi square value of 8.031 was obtained between the proportions of white American students, with large schools identifying fewer disruptive students. Hence, the twenty-eighth null hypothesis was rejected. A non-significant chi square value of 1.281 was obtained between the proportions of Hispanic-origin students. Therefore, the twenty-ninth null hypothesis was not rejected.

The thirtieth and thirty-first null hypotheses tested the relationship between the proportions of disruptive and non-disruptive male and female students in schools of different sizes. Non-significant chi square values were obtained. Hence, the thirtieth and thirty-first null hypotheses were not rejected.

In testing the thirty-second null hypothesis to determine the relationship between the incidence of disruptive behavior in urban and suburban schools, a non-significant chi square value of 0.0367 was obtained. Therefore, the thirty-second null hypothesis was not rejected.

In testing the thirty-third, thirty-fourth and thirty-fifth null hypotheses to determine the relationship

between the proportions of disruptive and non-disruptive lower, middle, and upper socio-economic status students respectively in urban and suburban schools, non-significant chi square values were obtained. Hence, the thirty-third, thirty-fourth, and thirty-fifth null hypotheses were not rejected.

In testing the thirty-sixth, thirty seventh, and thirty-eighth null hypotheses to determine the relation- ship between the proportions of disruptive and non-disruptive black American, white American, and Hispanic-origin stu- dents, respectively, in urban and suburban schools, non- significant chi square values were obtained. Therefore, the thirty-sixth, thirty-seventh, and thirty-eighth null hypotheses were not rejected.

The thirty-ninth and fortieth null hypotheses tested the relationship between the proportions of dis- ruptive and non-disruptive male and female students in urban and suburban schools. A non-significant chi square value of 1.37 was obtained between the proportions of male students. Hence, the thirty-ninth null hypothesis was not rejected. However, a significant chi square value of 5.0298 was obtained between the proportions of female students, with suburban schools reporting a higher incidence of disruptive female students. Therefore, the fortieth null hypothesis was rejected.

In testing the forty-first null hypothesis to determine the incidence of disruptive behavior in the seventh, eighth, and ninth grade a significant chi square value of 6.128 was obtained, with the eighth grade reporting the lowest incidence of disruptive behavior. Hence, the forty-first null hypothesis was rejected.

TABLE 46

REJECTED NULL HYPOTHESES IN ORDER OF
SIGNIFICANCE

Hypothesis Number	Chi Square Values	df	Significance
2	79.28	2	0.0000

The interpretation of the results of this study will be discussed in the following section of this chapter.

Discussion

The basic premise underlying this study was that a student's behavior in the school is a reflection of certain student characteristics beyond the school's control. Furthermore, certain school characteristics are related to the students' behavior. The socio-economic status, ethnicity, and sex of the student and the location, size, and ethnicity of the principal of the school were the independent variables used in this study. Another premise motivating this study was that the ethnicity of the student is incidental to his/her school behavior. Rather other student variables such as his/her socio-economic status (poverty and social deprivation) and sex, are related to the behavior of the student. Bias caused by a negative opinion held by some people about ethnic minorities has resulted in the aliena-tion of this type of student. Moreover, studies conducted in the last decade have reported unequal treatment of students by teachers, based on the student's ethnic origin and socio-economic status. Some of these studies include Jackson and Lahaderne (1967), Yee (1968), Brophy and Good (1970), and Rist (1970). Some of the results of this study supported these premises.

It should be remembered at this point that this study did not include the less serious types of misbehavior that result in a teacher's referral and end with a reprimand

at the assistant principal's office. This study was only concerned with the more severe types of disruptive behavior which warrant the removal of the student from the school environment.

In testing the first null hypothesis, stepwise multiple linear regression analysis was used to determine the difference between the socio-economic position, the ethnicity, the grade, and the sex of the student; the location, the size, and the ethnic origin of the principal of the school, and the frequency of disruptive behavior. The best predictors obtained in the regression analysis were (1) socio-economic position--lower; (2) sex--male; (3) ethnicity--non-Hispanic, (4) grade--non-eighth grader. Although these variables accounted for only 10.5% of the variance, the f value of each of the variables obtained in the regression analysis were statistically significant at the 0.01 level, with lower socio-economic status being the strongest predictor followed in order of importance by male sex, non-Hispanic, and non-eighth grader. This indicates that the student more prone to be suspended is of lower socio-economic status, male, non-Hispanic origin in the seventh or ninth grade. However, the importance of the non-Hispanic-origin variable should be reassessed due to the fact that most Hispanic-origin students were Cubans whose parents came from middle or upper socio-economic-status homes in

Cuba, and although in the lower socio-economic status at the time of this study, maintained their middle or upper class values. Since the first null hypothesis encompassed all the independent variables, it was not rejected.

Chi square was used to test the statistical significance of the rest of the null hypotheses. In testing the second hypothesis socio-economic status--lower was found to have the highest significant relationship with the incidence of disruptive behavior. This added support to the findings in the first null hypothesis and corroborated the results of studies conducted by Hollingshead (1949); Pearl, (1965); Hindelang (1971), and Lufler (1978).

In testing the third null hypothesis, ethnicity was found to have a highly significant relationship with the incidence of disruptive behavior, with black American students being the most disruptive. However, when socio-economic status is controlled, ethnicity was found to be incidental to disruptive behavior. This will be reviewed when the findings of the fifth, sixth, and seventh null hypotheses are discussed.

In testing the fourth null hypothesis to determine the relationship between students of different sex and the incidence of disruptive behavior, a significant chi square value of 22.94 significant at less than 0.0001 level was obtained. Male students were found to be more

disruptive than their female counterparts. This finding added support to the conclusions of Cloward and Ohlin (1960), Poorman et al. (1976), and Howard (1978).

In testing the fifth, sixth, and seventh null hypotheses that compared the differences between the disruptive and non-disruptive students of lower-, middle- and upper-socio-economic status; respectively, and different ethnic origin, only the fifth null hypothesis obtained a significant chi square of 8.97. Hispanic-origin students were significantly less disruptive than their black- and white-American counterparts. However, in the discussion of the first null hypothesis it was explained why this finding should be reassessed. No significant differences were found in the sixth and seventh null hypotheses. These findings indicate that there is no relationship between ethnicity and disruptive behavior once that socio-economic status is taken into consideration. This finding added support to studies conducted by Williams and Gold (1972) and Walberg et al. (1974).

In testing the eighth, ninth, and tenth null hypotheses that compared the difference between disruptive and nondisruptive male and female students of lower-, middle-, and upper-socio-economic status, respectively, the eighth null hypothesis obtained a significant chi square value. The ninth and tenth null hypotheses obtained nonsignificant values. This indicates that lower-socio-

economic male students are more disruptive than their
female counterparts.

In the eleventh, twelfth, and thirteenth null
hypotheses, black American and Hispanic-origin males
were found to be more disruptive than their female
counterparts. No significant difference was found in
the incidence of disruptive behavior of male and female
white American students.

Of the rest of the null hypotheses, only six
were found to be significant. In testing the fifteenth
null hypothesis, a significant chi square value of
4.195 was obtained. This indicates that white American
school principals identified a larger proportion of
lower-socio-economic status students than their counter-
parts.

In testing the eighteenth null hypothesis to
determine the relationship between disruptive and non-
disruptive black American students in schools with
principals of different ethnic origins, a significant
chi square value of 3.97 was obtained. White American
principals identified a greater proportion of disruptive
black American students than the non-white American
principals. In testing the nineteenth null hypothesis
to determine the relationship between disruptive and
nondisruptive white American students in schools with
non-white American principals, a significant chi square

value of 8.18 was obtained. This indicated that non-white American principals identified a greater proportion of disruptive white American students than their counterparts. However, this finding is misleading. A chi square was run to determine any statistically significant difference between the number of black American, white American, and Hispanic-origin students identified as disruptive by principals of different ethnic origins (see Table 47).

TABLE 47

BLACK AMERICAN, WHITE AMERICAN, AND HISPANIC-ORIGIN STUDENTS IDENTIFIED AS DISRUPTIVE IN SCHOOLS WITH PRINCIPALS OF DIFFERENT ETHNIC ORIGINS

		White American	Other	Row Total
Black	Count	37	22	59
	Row Pct.	62.7	37.3	48.0
	Col. Pct.	57.8	37.3	
	Tot. Pct.	30.1	17.9	
Hispanic	Count	20	14	34
	Row Pct.	58.8	41.2	27.6
	Col. Pct.	31.3	23.7	
	Tot. Pct.	16.3	11.4	
White	Count	7	23	30
	Row Pct.	23.3	76.7	24.4
	Col. Pct.	10.9	39.0	
	Tot. Pct.	5.7	18.7	
Total Column		64	59	123
Total Column Pct.		52.0	48.0	100.0

The obtained chi square of 13.224 was significant at less than 0.01 level. Although the total number of disruptive students identified by white American and non-white American

principals was very similar, the proportions of disruptive black American, white American, and Hispanic-origin students were not. Of the 64 students identified as disruptive by white-American principals, 57.8% were black American students, 31.3% were Hispanic-origin students, and only 10.9% were white American students. In contrast, of the 59 students identified as disruptive by non-white American princpals, 37.3% were black American students, 23.7% Hispanic-origin students, and 39% white American students. This finding adds support to the work of Shuttlesworth and Evans (1974) and Love (1977).

In testing the twenty-eighth null hypothesis to determine any difference between the proportions of disruptive white American students in schools of different sizes, a significant chi square value of 8.03 was obtained. A smaller proportion of disruptive white American students was identified in large schools. This finding is in contradiction with studies conducted by Baron (1975), the National Institute of Education (1977), and Kelly (1978). Therefore, it should be considered with great reservation.

In testing the fortieth null hypothesis to determine any difference between the proportion of disruptive and non-disruptive female students in urban and suburban schools, a significant chi square of 5.03 was obtained. A greater proportion of disruptive female students was identified in suburban schools. This finding, together

with the rest of the findings of the hypotheses in
Section V of Chapter IV are contrary to the findings
of studies conducted by Cloward and Ohlin (1960),
the Teacher Opinion Poll (1974), Koch (1975), and the
National Institute of Education (1977). Hence, they should
be considered with great reservation.

In testing the forty-first null hypothesis to
determine any difference in the incidence of disruptive
behavior in the seventh, eighth, and ninth grade, a
significant chi square value of 6.13 was obtained. The
eighth grade had the smallest proportion of disruptive
students.

Conclusions

Ten conclusions were drawn from this study.

1. The proportion of disruptive lower-socio-
economic-status students is significantly higher than the
proportions of disruptive middle- and upper-class students.
Furthermore, this variable has the highest relationship
with the incidence of disruptive behavior.

2. The proportion of disruptive male students is
significantly higher than the proportion of disruptive
female students.

3. The ethnicity of the student is incidental to
the incidence of disruptive behavior when socio-economic
status is taken into consideration.

4.   The proportion of disruptive lower-socio economic male students is significantly higher than the proportions of disruptive middle- and upper-socio-economic-status male students.

5.   The proportions of disruptive black American and Hispanic-origin male students are significantly higher than the proportions of disruptive black American and Hispanic-origin female students.

6.   The proportion of disruptive lower-socio-economic-status students in schools with white-American principals is significantly higher than the proportion of disruptive lower-socio-economic status students in schools with non-white American principals.

7.   The proportion of disruptive black American students in schools with white American principals is significantly higher than the proportion of disruptive black American students in schools with non-white American principals.

8.   There is no significant difference in the proportions of disruptive students of different ethnic origins in schools with non-white American principals.

9.   Schools with white American principals identify as disruptive a significantly higher proportion of black American students and a significantly lower pro-portion of white American students than schools with non-white American principals.

10. The proportion of disruptive students in the eighth grade is significantly lower than the proportions of disruptive students in the seventh and the ninth grade.

These conclusions connote the following implications:

1. Lower-socio-economic status is the most powerful predictor of disruptive behavior with male sex being the second.

2. Although demographic variables cannot be changed, the placement of teachers who understand underprivileged students and their psychological and social deficits in schools with a high lower-socio-economic-status school population should reduce the incidence of disruptive behavior, as proposed by Hendrix (1970).

3. Teachers whose strategies have been successful in dealing with disruptive behavior in lower-socio-economic areas should conduct workshops for teachers who work with lower-socio-economic-status students.

4. Efforts should be made to ascertain that bias and prejudice do not exist in the schools.

5. Since lower-socio-economic status is beyond the control of the school and it predetermines poor students' academic failures, as indicated in many studies, i.e., Coleman et al. (1966), Jencks (1972), and "Toward Equal Educational Opportunity" (1972), as well as their behavior in the school, i.e., Cloward & Ohlin (1960), Erickson

(1973), Howard (1978), the school alone should not be held accountable. Rather, all the institutions of society that have a vested interest in the education of our youth should share this responsibility.

Questions unanswered in this study which may warrant future research are:

1.   Does academic achievement influence the behavior of the student?

2.   To what extent does teacher competency determine the incidence of disruptive behavior in the classroom?

3.   To what extent does the competency of the assistant principal for administration of discipline determine the incidence of disruptive behavior in the schools?

4.   Why do schools with white American principals identify higher proportions of black American and lower-socio-economic-status students?

5.   All the research indicates that small size, as well as suburban schools are associated with a low incidence of disruptive behavior. This study did not yield the same results. In future research, it may be appropriate to duplicate the study of disruptive behavior in schools of different sizes in urban and suburban areas.

APPENDIX

SURVEY QUESTIONNAIRE

STUDENT'S NAME: _____

_____

(1) GRADE: _____   (2) SEX: MALE _____

                                                  FEMALE _____

(3) ETHNICITY:

           BLACK AMERICAN _____
           HISPANIC _____
           WHITE AMERICAN _____
           OTHER _____

(4) OCCUPATION OF THE STUDENT'S FATHER _____

(5) OCCUPATION OF THE STUDENT'S MOTHER _____

(6) LEVEL OF SCHOOLING COMPLETED BY STUDENT'S FATHER _____

(7) LEVEL OF SCHOOLING COMPLETED BY STUDENT'S MOTHER _____

(8) WAS THE STUDENT SUSPENDED THIS SCHOOL YEAR? YES _____

                                                 NO _____

(9) ETHNICITY OF SCHOOL PRINCIPAL: WHITE AMERICAN _____

                                    OTHER _____

BIOGRAPHICAL SKETCH

The author was born in Camaguey, Cuba, on August 2, 1932. At age 16 he dropped out of school. He came to the United States in 1952 where he was graduated from Miami Senior High School in 1953. He later received a Bachelor of Administration degree from the University of Miami in 1955 and returned to Cuba, remaining there until 1960 when he came back to the United States. He began working for the Dade County Public Schools as a substitute teacher in 1960. He worked as a classroom teacher at Miami Senior High School from 1961 until 1970, while working toward certification at Barry College. He received his Master of Science from Barry College in 1973. From 1970 through 1974 the author worked as a visiting teacher for the Dade County Public Schools, and from 1974 to the time of this dissertation he has been an assistant principal. He is presently working in an inner-city junior high school. Prior to completion of this dissertation, in 1976, the author received his Specialist of Education degree from the University of Florida.
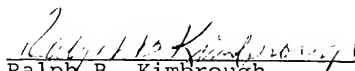

I certify that I have read this study and that in my opinion it conforms to acceptable standards of scholarly presentation and is fully adequate, in scope and quality, as a dissertation for the degree of Doctor of Philosophy.

S. Kern Alexander, Chairman
Professor of Educational
  Administration

I certify that I have read this study and that in my opinion it conforms to acceptable standards of scholarly presentation and is fully adequate, in scope and quality, as a dissertation for the degree of Doctor of Philosophy.

Vance A. Hines, Cochairman
Professor of Foundations of
  Education

I certify that I have read this study and that in my opinion it conforms to acceptable standards of scholarly presentation and is fully adequate, in scope and quality, as a dissertation for the degree of Doctor of Philosophy.

Ralph B. Kimbrough
Professor of Educational
  Administration

This dissertation was submitted to the Graduate Faculty of the Department of Educational Administration in the College of Education and to the Graduate Council, and was accepted as partial fulfillment of the requirements for the degree of Doctor of Philosophy.

August 1978
